1 Introduction ...

Introduction 1 / 6

The homologous series $A_nB_nO_{3n+2} = ABO_x$ stands for a special class of perovskite-related layered oxides. The layers comprise an arrangement of BO_6 octahedra which are $[110]_{\text{perovskite}}$ oriented along the c -axis. The index or structure type n describes the thickness of the layers which are n BO_6 octahedra thick along the c -axis. For $n = \infty$ the non-layered perovskite structure ABO_3 is obtained.

Why are oxides of the type $A_nB_nO_{3n+2} = ABO_x$ interesting ?

- They comprise the highest- T_c ferroelectrics such as the $n = 4$ type $La_4Ti_4O_{14} = La_2Ti_2O_7 = LaTiO_{3.5}$ with $T_c = 1770$ K
- They comprise quasi-1D metals where the delocalized electrons are embedded in a ferroelectric-like environment with high dielectric permittivity. An example is the $n = 5$ type $Sr_5Nb_5O_{17} = SrNbO_{3.4}$
- The quasi-1D metals display particular photoinduced properties: Teguh Citra Asmara et al., to be published in Communications Physics (2020)
- They might have a potential to create multiferroics and / or superconductors

Introduction 2 / 6

Why are oxides of the type $A_nB_nO_{3n+2} = ABO_x$ interesting ? continued

- They allow the fabrication of novel micro or nano patterned systems by an electron beam such as conducting $n = \infty$ perovskite type $SrNbO_3$ micro/nano pillars in a ferroelectric $n = 4$ type $SrNbO_{3.5}$ matrix
- There are non-integral series members such as the $n = 4.5$ type quasi-1D metal $SrNbO_{3.45}$ which comprise an ordered stacking sequence of layers with different thickness
- Many compounds can be synthesized in a single phase and crystalline form via a solidification from the melt by floating zone melting
- There are many possible chemical compositions including non-stoichiometric compounds
- Presence of a partial or full occupational order
 - at the A or B site when there are cations A' and A'' or B' and B'' with a different valence such as $B = (Ti^{4+}, Fe^{3+})$
 - at the O site in case of oxygen vacancies

Introduction 3 / 6

This work presents concepts, results, and materials from own research and from other scientists and publications. Several materials synthesis experiments are described in detail with many pictures and several fast mode and real time videos from the floating zone melting process in a Cyberstar mirror furnace.

Examples from the content of this work:

As an extension of the already reported $n = 6$ type $\text{La}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ related melt-grown $n = 6$ type materials $\text{Ln}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ ($\text{Ln} = \text{Ce}, \text{Pr}, \text{Nd}, \text{Sm}, \text{Sm}_{0.9}\text{Eu}_{0.1}, \text{Eu}$) and $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ are presented.

A focus topic in this paper is $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ and related compounds.

$\text{Sr}_5\text{Nb}_5\text{O}_{16}$ is reported by K. Schüchel and Hk. Müller-Buschbaum in *Zeitschrift für Anorganische und Allgemeine Chemie* **528** (1985) 91.

Small crystals were obtained by a very special technique, the non-centrosymmetric crystal structure was determined by single crystal x-ray diffraction, and physical properties are not reported.

Introduction 4 / 6

As already communicated in

Progress in Solid State Chemistry 36 (2008) 253

- the crystal structure of the non-centrosymmetric $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ can be considered as an oxygen-deficient variant of the $n = 5$ type and centrosymmetric quasi-1D metal $\text{SrNbO}_{3.4} = \text{Sr}_5\text{Nb}_5\text{O}_{17} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$ with fully ordered oxygen vacancies
- attempts to prepare the Schückel-Müller-Buschbaum phase $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ via the melt were unsuccessful

In contrast to the quasi-1D metal $\text{Sr}_5\text{Nb}_5\text{O}_{17}$ a layer or slab of $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ comprises along the c -axis an asymmetric distribution of the

- Nb^{4+} ($4d^1$) and Nb^{5+} ($4d^0$) ions
- Nb – O polyhedra distortions

Maybe these particular details of this structure type and its reported non-centrosymmetry can bring forth special physical properties.

Introduction 5 / 6

To enable the verification of the crystal structure reported by K. Schücker and Hk. Müller-Buschbaum and the study of the physical properties it was tried to prepare related melt-grown compounds.

This work presents five melt-grown Sr- and O-deficient $n = 5$ type materials which are related to $\text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ and appear single phase within the detection limit of powder x-ray diffraction:

The temperature dependence of the magnetic moment or susceptibility of these five compounds suggests that they are potentially quasi-1D metals. The two latter are Sr-deficient Schücker-Müller-Buschbaum type phases because their oxygen content is 64.

Introduction 6 / 6

Examples of crystalline pieces from the melt-grown materials:

$\text{Sr}_{19}\text{Nb}_{19}\text{WO}_{66}$ 6.9

$\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ 11.1

Number of d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$ per formula

For comparison: 4 in $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$ and 12 in $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$

These materials give rise to several questions such as: Have the compounds with oxygen content 64 the same non-centrosymmetric but Sr-deficient crystal structure as that of $\text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ reported by K. Schüchel and Hk. Müller-Buschbaum ? Do the W ions occupy specific *B* or Nb sites ? Are there also related insulating materials which are potentially ferroelectric, magnetoelectric, or multiferroic ?

2 The crystal structure of $A_n B_n O_{3n+2} = ABO_x$ and other perovskite-related layered oxides...

The perovskite structure of compounds of the type ABX_3 or ABO_3

2D sketch of perovskite-related layered oxides of the type

Special features of $A_nB_nO_{3n+2} = ABO_x$ when compared to the other homologous series:

- Marked structural in-plane anisotropy, see also page 34
- The structure type n can be altered by changing only the oxygen content x . This allows a special kind of micro or nano patterning by an electron beam which is presented in part 8

3 How the name
Carpenter-Galy phases
for oxides of the type
 $A_n B_n O_{3n+2} = ABO_x$
comes about ...

A name for the oxides of the type $A_nB_nO_{3n+2} = ABO_x$: Carpy-Galy phases

To the best of our knowledge the first publications about oxides of the type $A_nB_nO_{3n+2}$ were published by Alain Carpy et al. in 1972 and 1973 for $Ca_2Nb_2O_7$ and compounds in the system $Ca_2Nb_2O_7 - NaNbO_3$:

Alain Carpy, Pierre Amestoy, and Jean Galy
Contribution a l'étude du pyroniobate de calcium $Ca_2Nb_2O_7$ Paper in French
Comptes Rendus des Seances de
L'Academie des Sciences, Paris, Serie C,
275 (14) (1972) 833 - 835

Alain Carpy, Pierre Amestoy, and Jean Galy
Systeme $Ca_2Nb_2O_7 - NaNbO_3$: synthèse et
etude radiocristallographique de membres de
la serie $A_nB_nX_{3n+2}$ (n =4, 5, 6) Paper in French
Comptes Rendus des Seances de
L'Academie des Sciences, Paris, Serie C,
277 (1) (1973) 501 - 506

Many compounds and publications are presented and cited in

V. A. Isupov , *Ferroelectrics* 220 (1999) 79 - 103 <https://doi.org/10.1080/00150199908007997>

F. Lichtenberg et al. , *Progress in Solid State Chemistry* 29 (2001) 1 - 70 and 36 (2008) 253 - 387

Presentation of a lab for the synthesis and study of melt-grown oxides, published by the library of the ETH Zurich / ETH Research Collection in 2017 (438 pages):

<https://dx.doi.org/10.3929/ethz-a-010817148>

Experimental details and used equipment at the ETH Zurich like

- an analytical balance Mettler Toledo MS 204 for weighing powders
- special mortars and pestles for the mingling of powders
- custom-made pressing dies made of magnesia-stabilized zirconia or quartz glass for the preparation of polycrystalline sintered rods for floating zone melting in a mirror furnace
- a laboratory chamber furnace Linn High Therm VMK 1600
- a GERO tube furnace
- Cyberstar mirror furnace
- custom-made sample holders made of yttria-stabilized zirconia and custom-made screws made of Pt-Rh for the fixation and centering of polycrystalline sintered rods at the lower and upper shaft of the mirror furnace
- an oxygen analyzer ZIROX SGM7 to measure the oxygen content of argon at the gas outlet of the GERO tube furnace and the Cyberstar mirror furnace
- a thermogravimetric analyzer NETZSCH TG 209 F1 Libra and how to determine the oxygen content of oxides by thermogravimetry
- the mechanical fixation of a sample within a straw by pieces of another straw for magnetic measurements in a SQUID magnetometer
- the measurement of the magnetic moment $M(T)$ or $M(H)$ of a sample by a Quantum Design SQUID magnetometer MPMS3

are presented in <https://dx.doi.org/10.3929/ethz-a-010817148>

Examples of furnaces

Non-gas-tight laboratory chamber furnace

For removing moisture of starting materials, pre-reactions, calcination, sintering or synthesis of polycrystalline materials in air

Gas-tight tube furnace

For preparation or sintering of polycrystalline materials under various non-air atmospheres such as oxygen, argon, argon plus hydrogen, or vacuum

Gas-tight mirror furnace / floating zone melting furnace

For synthesis of crystalline oxides via a solidification from the melt under various atmospheres like oxygen, air, argon, argon plus hydrogen or vacuum

Sketch of the sample preparation

- 1) ☺ It starts always with an idea about a known, new or apriori hypothetical oxide material, i.e. devise a chemical composition such as $\text{La}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ or $\text{Sr}_5\text{Nb}_5\text{O}_{17}$
- 2) Select appropriate starting materials from commercially available powders such as oxides La_2O_3 , TiO_2 , Fe_2O_3 or Nb_2O_5 , carbonates like CaCO_3 , and / or metals such as Nb
- 3) Calculate the amounts (mass, weight) of the selected starting materials according to the devised or desired chemical composition
- 4) Weighing the calculated amounts of the starting materials by a spatula, weighing paper, and an analytical balance
- 5) Mingle the weighed starting materials by a mortar and pestle. If steps 6 - 8 are omitted, then a part of the as-mingled starting materials is pressed into two rods and it is continued with step 9
- 6) Pre-reaction in air: Heat the mingled starting materials in a laboratory chamber furnace to elevated temperatures

Sketch of the sample preparation

- 7) Grind the pre-reacted starting materials into powder and mingle it by a mortar and pestle – in some cases another starting material is added to the pre-reacted starting materials
- 8) Press a part of the powder obtained in step 7 into two rods
- 9) Sinter the as-pressed rods at elevated temperatures under an appropriate atmosphere such as under air in a laboratory chamber furnace or under argon in a tube furnace or molybdenum furnace
- 10) Try to synthesize the devised or desired oxide material in a crystalline form via a solidification from the melt by processing the sintered rods by floating zone melting in a mirror furnace under an appropriate atmosphere such as air or argon. In some cases reduced mixed-valence titanates or niobates can be prepared by processing sintered rods with a fully oxidized composition by floating zone melting under argon plus hydrogen

Examples of commercially available starting materials

Fe_2O_3 powder

WO_3 powder

SrCO_3 powder

Nd_2O_3 powder

Nb powder

Storage of starting materials in an alumina crucible in a desiccator

Pressing dies for the preparation of rods for the mirror furnace

Custom-made pressing dies made of technical ceramics

Type C with square punch for other samples

Type B with rectangular punch for seed rods with length 35 mm and width 3,5 mm

Type A with rectangular punch for feed rods with length 85 mm and width 4,5 mm

Yellow parts made of magnesia stabilized zirconia (FRIATEC FRIALIT FZM) by FRIATEC AG (Germany), purchased and delivered from stone-ware gmbh (Switzerland) <https://dx.doi.org/10.3929/ethz-a-010817148>

Metal frames made in the metal workshop of the Department of Materials of the ETH Zurich by C. Roth and M. Elsener

Several types of lower punches on which the powder is pressed

Lower punches for the pressing die type A (feed rod), type B (seed rod) and type C

Lower punches
made of alumina
(FRIATEC FRIALIT F 99,7)
- usable up to 1950 °C

Lower punches made of
yttria stabilized zirconia
(FRIATEC DEGUSSIT FZY)
- usable up to 1500 °C

Made by FRIATEC AG (Germany), purchased and
delivered from stone-ware gmbh (Switzerland)

<https://dx.doi.org/10.3929/ethz-a-010817148>

Example of an as-pressed feed rod for the mirror furnace

- 3 Rectangular rod with a continuous hole - made of pressed powder
Chemical composition of the pressed powder in this example: $0,6 \text{ Nb} + 0,2 \text{ Nb}_2\text{O}_5$
- 2 Lower punch - made of alumina (FRIATEC FRIALIT F 99,7)
- 1 Base plate - made of magnesia stabilized zirconia (FRIATEC FRIALIT FZM)

The powder was pressed with a pressing force of 1 kN. The as-pressed rod is mechanically not stable. If it is touched in a not very careful way, then it becomes damaged or destroyed. However, the rod is needed in a mechanically stable form. Therefore the lower punch and the pressed rod will be placed into an alumina box and heated to an appropriate high temperature under a suitable atmosphere which results in sintering and chemical solid state reactions

Feed rod and seed rod for the mirror furnace before and after sintering

Pressed rods on their lower alumina punch in an alumina box before sintering

Chemical composition of the powder in this example: $0,6 \text{ Nb} + 0,2 \text{ Nb}_2\text{O}_5$

Pressed rods on their lower alumina punch in an alumina box after sintering them for 1 h at $1150 \text{ }^\circ\text{C}$ under argon

The color change of the rods from white-grey to black is due to chemical solid state reactions like $0,6 \text{ Nb} + 0,2 \text{ Nb}_2\text{O}_5 \rightarrow \text{NbO}$

<https://dx.doi.org/10.3929/ethz-a-010817148>

Another pressing dies for the preparation of rods for the mirror furnace

Custom-made pressing dies made of glass

Type A2 with rectangular punch for feed rods with length 90 mm and width 5 mm

Type B2 with rectangular punch for seed rods with length 40 mm and width 4 mm

Glass parts purchased and delivered from EMATAG AG (Switzerland)

Metal frames, trays and other metal parts made in the metal workshop of the Department of Materials of the ETH Zurich by C. Roth and M. Elsener

Example of an as-pressed feed rod for the mirror furnace

An as-pressed rod inside the pressing die when the metal frame is removed. The applied pressing force was 1 kN

View when the side panels are removed:

- 4 Control cabinet
- 5 Movable control unit for lamp power and fast motion of seed and feed rod
- 6 Turbo pumping station

Cyberstar mirror furnace – Casing open and mirrors M1 and M2 locked

Cyberstar mirror furnace – Mirrors unlocked

1 Elliptical and gold-coated mirror

2 Lamp
 $P_{\max} = 1000 \text{ W}$

3 Quartz glass tube

4 Upper shaft

5 Lower shaft

Mirrors and lamps are cooled by cooling water and a flow of compressed air

- Mirrors focus radiation from lamps into a small volume. If a material is located at that volume, then it can be molten if the lamp power is high enough
- Heating-up and melting of a material takes mainly place by its infrared absorption
- Mirrors are gold-coated because that enhances their infrared reflectivity

Synthesis of crystalline materials by a mirror furnace requires desired chemical composition in form of two rods

Example of two polycrystalline sintered rods with same chemical composition such as $\text{La}_2\text{Ti}_2\text{O}_7$

Fixation of the rods at the lower and upper shaft by special sample holders ...

Powder x-ray diffraction

Preparation of powder for the measurement

A sample holder from PANALYTICAL for powder x-ray diffraction. The inner part (gray) is made of single crystalline silicon with an orientation which displays no diffraction peaks in the measurement range of the diffractometer. The diameter of the inner deepening (D) is 15 mm

The inner deepening of the sample holder is loaded with a small powder heap. The powder can be dispersed by adding a few droplets of ethanol and a subsequent manual horizontal oscillating motion

The powder is dispersed in a flat manner within the inner deepening. It is important that the powder is on the same height as the gray silicon (S). Now it is ready for a powder XRD measurement

Powder x-ray diffraction

To verify the accuracy of the measured peak positions each measurement or series of measurements was followed by a separate measurement with a polycrystalline silicon sample from PANALYTICAL

Solid disk from PANALYTICAL made of polycrystalline silicon. Its diameter is 3 cm

5 Insulating, ferroelectric,
and potential multiferroic
Carpenter-Gajdhar phases

5.1 Insulators and ferroelectrics ...

$A_n B_n O_{3n+2} = ABO_x$ type insulators and ferroelectrics ($B = \text{Ti}^{4+}, \text{Nb}^{5+}, \text{Ta}^{5+}$)

- The highest- T_c ferroelectrics are $n = 4$ type oxides, e.g. $\text{LaTiO}_{3.50}$ with $T_c = 1770$ K and $\text{CaNbO}_{3.50}$ which is ferroelectric up to its melting point of 1850 K !

S. Nanamatsu et al., *Ferroelectrics* 8 (1974) 511 • S. Nanamatsu and M. Kimura, *J. Phys. Soc. Jpn.* 36 (1974) 1495

Definition of highest- T_c ferroelectrics: Compounds with $T_c > T_c(\text{LiNbO}_3) = 1480$ K

- Ferroelectrics $\rightarrow n$ is an even number like $n = 2, 4, 6$ (non-centrosymmetric)
Antiferroelectrics $\rightarrow n$ is an odd number like $n = 3, 5, 7$ (centrosymmetric)

- Compounds with non-integral n

e.g. $\text{CaNb}_{0.89}\text{Ti}_{0.11}\text{O}_{3.44}$ ($n = 4.5$) M. Nanot et al. , *Journal of Solid State Chemistry* 28 (1979) 137

- Single phase bulk materials known for $n = 2, 3, 4, 4.33, 4.5, 5, 6, 7$

- Complex structural details like incommensurate modulations

e.g. in $\text{SrNbO}_{3.50}$ ($n = 4$) P. Daniels et al. , *Acta Crystallographica Section B* 58 (2002) 970

- Another ions $B' = \text{Al}^{3+}, \text{Fe}^{3+} \dots$ can occupy the B site:

$B = (\text{Ti}, \text{Nb}, \text{Ta})_{1-y} B'_y$ whereby so far $y \leq 0.33$

Why are there so few magnetic ferroelectrics ?

Why are there so few magnetic ferroelectrics ?

Nicola A. Hill

The Journal of Physical Chemistry B 104 (2000) 6694 - 6709

<https://doi.org/10.1021/jp000114x>

Abstract

Multiferroic magnetoelectrics are materials that are both ferromagnetic and ferroelectric in the same phase. As a result, they have a spontaneous magnetization that can be switched by an applied magnetic field, a spontaneous polarization that can be switched by an applied electric field, and often some coupling between the two. Very few exist in nature or have been synthesized in the laboratory. In this paper, we explore the fundamental physics behind the scarcity of ferromagnetic ferroelectric coexistence. In addition, we examine the properties of some known magnetically ordered ferroelectric materials. We find that, in general, the transition metal d electrons, which are essential for magnetism, reduce the tendency for off-center ferroelectric distortion. Consequently, an additional electronic or structural driving force must be present for ferromagnetism and ferroelectricity to occur simultaneously.

Epitaxial BiFeO₃ (Fe³⁺ / 3d⁵) Multiferroic Thin Film Heterostructures

Epitaxial BiFeO₃ Multiferroic Thin Film Heterostructures

Science 299 (2003) 1719 - 1722

<https://doi.org/10.1126/science.1080615>

Abstract

Enhancement of polarization and related properties in heteroepitaxially constrained thin films of the ferroelectromagnet, BiFeO₃, is reported. Structure analysis indicates that the crystal structure of film is monoclinic in contrast to bulk, which is rhombohedral. The films display a room-temperature spontaneous polarization (50 to 60 microcoulombs per square centimeter) almost an order of magnitude higher than that of the bulk (6.1 microcoulombs per square centimeter). The observed enhancement is corroborated by first-principles calculations and found to originate from a high sensitivity of the polarization to small changes in lattice parameters. The films also exhibit enhanced thickness-dependent magnetism compared with the bulk. These enhanced and combined functional responses in thin film form present an opportunity to create and implement thin film devices that actively couple the magnetic and ferroelectric order parameters.

Some structural and physical properties of Fe_2O_3 ($\text{Fe}^{3+} / 3d^5$)

α - Fe_2O_3 (Hematite)

- Corundum type structure
- Neel temperature $T_N \approx 685$ °C
- Low temperature magnetic transition $T_C \approx 260$ K
- Weak ferromagnetic between T_C and T_N

γ - Fe_2O_3 (Maghemite)

- Cation-deficient spinel structure
- Ferrimagnetic with $T_C \approx 950$ K
- Magnetic moment about 2.5 Bohr magnetons per formula unit
- Used as magnetic pigment in electronic recording media

Polar (!) ε - Fe_2O_3

- So far prepared only as nanoparticles and thin films
- Difficult to prepare in a single phase form
- At room temperature non-centrosymmetric GaFeO_3 structure
- Ferrimagnetic with $T_C \approx 510$ K
- Coupling between magnetic and dielectric properties

5.3 Materials in the context of potential multiferroic Carpenter-Galvay phases

5.3 Materials in the context of potential multiferroic Carpy-Galy phases

5.3.1 Compounds in the system La – Ti⁴⁺ – Fe³⁺ (Mn³⁺) – O like the $n = 6$ type

Ti⁴⁺ (3d⁰) and Fe³⁺ (3d⁵) insulators of the type La_n(Ti,Fe)_nO_{3n+2} = La(Ti,Fe)O_x

Reported properties of melt-grown $\text{La}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ ($n = 6$) by X. Cheng et al.

Multiferroic properties of the layered perovskite-related oxide $\text{La}_6(\text{Ti}_{0.67}\text{Fe}_{0.33})_6\text{O}_{20}$

Xiangyi Cheng et al. , Journal of Materials Chemistry C 3 (2015) 4482 - 4489

<https://doi.org/10.1039/C5TC00188A>

Abstract: The magnetic and electrical properties of the layered perovskite-related oxide $\text{La}_6(\text{Ti}_{0.67}\text{Fe}_{0.33})_6\text{O}_{20}$ are investigated. The material possesses the structure of six ABO_3 layers with iron ions concentrated towards the center of the slabs. The valence state of La, Ti and Fe ions was determined using X-ray photoelectron spectroscopy. The “glassy” magnetic behavior of $\text{La}_6(\text{Ti}_{0.67}\text{Fe}_{0.33})_6\text{O}_{20}$ can be understood by the coexistence and competition between two different types of interaction, which originate from both the antiferromagnetic interactions between $\text{Fe}^{3+} - \text{O} - \text{Fe}^{3+}$ in the central layers of the slabs and ferromagnetic coupling that is induced by the oxygen vacancies from the titanium ion enrichment zone at the borders, owing to the nonrandom distribution of magnetic Fe^{3+} ions. The observed ferromagnetism can be ascribed to the ferromagnetic coupling and spin canting of the antiferromagnetic coupling via the Dzyaloshinskii–Moriya interaction. The frequency-dependent behavior of the dielectric loss peak in $\text{La}_6(\text{Ti}_{0.67}\text{Fe}_{0.33})_6\text{O}_{20}$ manifests itself as a thermally activated relaxation process. The $P - E$ hysteresis loops and local piezoresponse loops confirm the ferroelectric behavior of $\text{La}_6(\text{Ti}_{0.67}\text{Fe}_{0.33})_6\text{O}_{20}$

Reported properties of melt-grown $\text{La}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ ($n = 6$) by X. Cheng et al.

P(E) curve at 100 Hz and room temperature from dielectric measurements

Citation from the paper:

The sample exhibits FE hysteresis loops at room temperature even though the loops are not really saturated, which represents a partial reversal of the polarization. It can be seen that remnant polarization increases gradually with an increase in the electric field, indicating that the electric field provides higher level of driving power, which is responsible for the reversal of ferroelectric domains. In addition, leaky behavior is deduced from the curvature of the polarization maxima at higher fields. The lossy character of the sample may result from the existence of oxygen vacancies

5.3.2 Melt-grown $n = 6$ type

and $Ca_6 Nb_5 FeO_{20}$ prepared at the ETH Zurich ...

Melt-grown $n = 6$ type compositions $Ln_6Ti_4Fe_2O_{20}$

The lanthanides Ln from La to Eu:

La	Ce	Pr	Nd	Pm	Sm	Eu
57	58	59	60	61	62	63

In 2014 - 2016 and 2018 polycrystalline sintered rods with composition

- $Ce_6Ti_4Fe_2O_{20}$
- $Pr_6Ti_4Fe_2O_{20+y}$
- $Nd_6Ti_4Fe_2O_{20}$
- $Sm_6Ti_4Fe_2O_{20}$
- $Sm_{5.4}Eu_{0.6}Ti_4Fe_2O_{20}$
- $Eu_6Ti_4Fe_2O_{20}$
- $Ca_6Nb_5FeO_{20}$

$Nb^{5+} / 4d^0$
$Fe^{3+} / 3d^5$
$Ti^{4+} / 3d^0$

$Eu^{3+} / 4f^6$
$Sm^{3+} / 4f^5$
$Nd^{3+} / 4f^3$
$Pr^{3+} / 4f^2$

were processed at the ETH Zurich by floating zone melting in a Cyberstar mirror furnace. Starting materials (powder) were CeO_2 , $Pr_6O_{11} = PrO_{1.83}$ or PrO_x with thermogravimetrically determined oxygen content x , Nd_2O_3 , Sm_2O_3 , Eu_2O_3 , TiO , TiO_2 , Fe_2O_3 , $CaCO_3$, and Nb_2O_5 with a purity $\geq 99.9\%$. The oxygen content of Fe_2O_3 was verified by a thermogravimetric reduction to Fe as described on page 62 (Fig. 41) in <https://dx.doi.org/10.3929/ethz-b-000220998>. To remove moisture from the starting materials – apart from PrO_x and TiO – they were heated at appropriate temperatures under air and subsequently stored in a desiccator.

One of several unsuccessful attempts to prepare $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

Most lanthanide oxides are commercially available as Ln_2O_3 (Ln^{3+}) and therefore one can try to prepare $\text{Ln}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ in the following way under air:

However, cerium oxide is offered only as CeO_2 (Ce^{4+}) and it is relatively stable, even at high temperatures in the presence of other elements. One of several potential approaches to synthesize $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ is the following:

The oxygen content of TiO and that of the prepared powder mixture $6 \text{CeO}_2 + 3 \text{TiO} + \text{TiO}_2 + \text{Fe}_2\text{O}_3 = \text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ was verified thermogravimetrically.

One of several unsuccessful attempts to prepare $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

As-pressed rods
with composition
 $6 \text{CeO}_2 + 3 \text{TiO} + \text{TiO}_2 + \text{Fe}_2\text{O}_3$
on their lower punch made of
sapphire in an alumina box. The

 1200°C under argon in the
GERO tube furnace

Run / Sample No. 831

One of several unsuccessful attempts to prepare $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

Log-linear plot of recorded data of a tube furnace run on 31 October and 1 November 2018 with rods No. 831 on lower punches in an alumina box covered with a Nb sheet. Before starting the run: 2 × evacuated ($3.5 \times 10^{-3} / 2.0 \times 10^{-3}$ mbar at the gas outlet after 6 / 6 min) and flushed with Ar. Gas (Ar) flow rate 400 sccm (24 L / h). Heating and cooling rate 250 °C / h (set values). Dwell time 2 h at 1200 °C . The O_2 content of Ar at the gas outlet becomes zero at elevated temperatures because the Nb sheet getters oxygen. Ar purity 6.0

One of several unsuccessful attempts to prepare $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

Sintered rods with composition $6 \text{CeO}_2 + 3 \text{TiO} + \text{TiO}_2 + \text{Fe}_2\text{O}_3 = \text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

Run / Sample No. 831

Prepared at the ETH Zurich in 2018

One of several unsuccessful attempts to prepare $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

Run / Sample No. 831

Fast mode video (~ 2 min) of the overall run (~ 4 h) in the Cyberstar mirror furnace. The video is only running in the ppsx type version of this publication, see page 2

The composition of the polycrystalline sintered rods is $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ and the floating zone melting is performed under flowing Ar

Lamp power to maintain the molten zone: $2 \times (404 - 325)$ W

Speed of the lower shaft and seed rod (crystal growth speed): 14 mm / h

The gas outlet is equipped with an oxygen analyzer ZIROX SGM7 and at the beginning of the run the oxygen content of argon was about 1 ppm. Subsequently it increased stepwise to 25 ppm, i.e. the solid and / or molten material did release somewhat oxygen

One of several unsuccessful attempts to prepare $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

45 mm long as-grown crystalline material (1), polycrystalline see rod (2),
and remaining part of the polycrystalline feed rod (3)

Run / Sample No. 831

Prepared at the ETH Zurich in 2018

One of several unsuccessful attempts to prepare $n = 6$ type $\text{Ce}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

45 mm long as-grown crystalline material

Sample No. 831

A crystalline piece from section C6.

Powder x-ray diffraction of pulverized crystalline pieces from section C6 indicates the presence of a $\text{Ce}(\text{Ti},\text{Fe})\text{O}_3$ perovskite type phase, a $n = 5$ type phase $\text{Ce}_5\text{Ti}_5\text{O}_{17}$ which is reported in Progress in Solid State Chemistry 36 (2008) 253, and another unidentified phases. The presence of several phases in this material is also suggested by the non-constant lamp power $2 \times (404 - 325)$ W to maintain the molten zone during the mirror furnace run. This indicates an incongruent melting and solidification and therefore a multiphase material.

Synthesis of melt-grown $n = 6$ type $\text{Pr}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ and $\text{Nd}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

Most lanthanide oxides such as Nd_2O_3 are commercially available as Ln_2O_3 (Ln^{3+}) and therefore one can try to prepare $\text{Ln}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ in the following way under air:

However, praseodymium oxide is offered only as $\text{Pr}_6\text{O}_{11} = \text{PrO}_{1.83}$ and it is advisable to study its actual composition or oxygen content by thermogravimetry. At elevated temperatures and in the presence of other elements Pr_6O_{11} releases oxygen and all Pr ions adopt the valence state Pr^{3+}

Thermogravimetric study of $\text{Pr}_6\text{O}_{11} = \text{PrO}_{1.83}$ or PrO_x

$\text{Pr}_6\text{O}_{11} = \text{PrO}_{1.83}$ from various suppliers was analyzed thermogravimetrically, i.e. they were reduced under flowing argon plus hydrogen towards $\text{Pr}_2\text{O}_3 = \text{PrO}_{1.50}$. These studies did reveal a significant deviation from their assumed composition. If the difference between the assumed and actual composition is expressed in terms of an assumed formula PrO_x , then the investigated powder correspond to $x = 2$ and $x = 2.07$. Their actual composition is, however, most probably something like $\text{PrO}_x\text{H}_y\text{C}_z$. Nevertheless, the results from thermogravimetric analysis enable a correct stoichiometric calculation by taking into account the weight difference between the assumed and actual composition.

Melt-grown $n = 6$ type materials $\text{Pr}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ and $\text{Nd}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

$\text{Pr}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ Sample No. 727

$\text{Nd}^{3+} / 4f^3$
 $\text{Pr}^{3+} / 4f^2$
 $\text{Fe}^{3+} / 3d^5$
 $\text{Ti}^{4+} / 3d^0$

$\text{Nd}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ Sample No. 731

Prepared at the ETH Zurich in 2014 • Grown with 10 - 14 mm / h under flowing 90 % Ar + 10 % O₂ • Powder x-ray diffraction indicates in both cases a single phase $n = 6$ type material

Both mirror furnace runs were overall relatively difficult because the molten zone did often break down. Therefore after the normal run a **reverse run** was performed, i.e. the crystalline material was molten again and converted via a molten zone into a new crystalline material which grew onto the bottom end of the remaining part of the feed rod

Melt-grown $n = 6$ type materials $\text{Sm}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ and $\text{Sm}_{5.4}\text{Eu}_{0.6}\text{Ti}_4\text{Fe}_2\text{O}_{20}$

$\text{Sm}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$
Sample No. 718

Prepared at the ETH Zurich in 2014
Grown with 14 mm / h under
flowing synthetic air

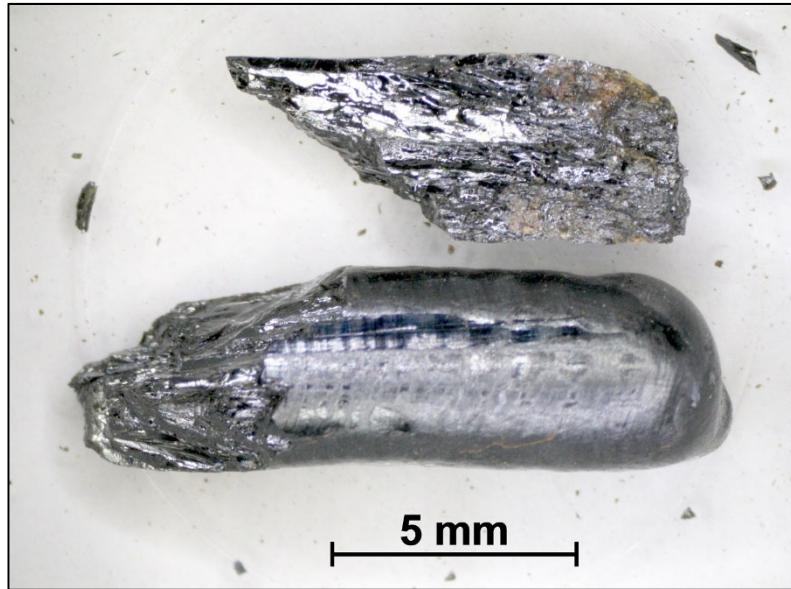

$\text{Sm}_{5.4}\text{Eu}_{0.6}\text{Ti}_4\text{Fe}_2\text{O}_{20}$
Sample No. 752

Prepared at the ETH Zurich in 2015
Grown with 10 mm / h under
flowing 90 % Ar + 10 % O_2

Powder x-ray diffraction indicates in both cases an $n = 6$ type material. In both cases there is 1 unindexed peak at $2\Theta = 32.75^\circ$ with 2 % relative intensity. This suggests the presence of small amounts of $(\text{Sm},\text{Eu})\text{FeO}_3$ because its highest intensity peak is located at $2\Theta \approx 32.7^\circ$

$n = 6$ type $\text{Sm}_{5.4}\text{Eu}_{0.6}\text{Ti}_4\text{Fe}_2\text{O}_{20}$ • Melt-grown under normal and high pressure

Sample No. 753

Prepared at the ETH Zurich in 2015

Grown with 10 mm / h under flowing

90 % Ar + 10 % O₂ with high pressure 9 - 10 bar

Powder x-ray diffraction indicates in both cases an $n = 6$ type material

All observed peaks fit to an $n = 6$ type structure. This indicates that the synthesis under high pressure has suppressed the formation of a small amount of (Sm,Eu)FeO₃

Sample No. 752

Prepared at the ETH Zurich in 2015

Grown with 10 mm / h under flowing

90 % Ar + 10 % O₂

1 unindexed peak at $2\theta = 32.75^\circ$ with 2 % relative intensity. This suggests the presence of a small amount of (Sm,Eu)FeO₃ because its highest intensity peak is located at $2\theta \approx 32.7^\circ$

Melt-grown materials with $n = 6$ type composition $\text{Eu}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$

Pieces from sample No. 720 grown with 8 mm / h under flowing synthetic air and normal pressure. Powder x-ray diffraction indicates a multiphase material which consists mainly of a cubic pyrochlore $\text{Eu}_2\text{Ti}_2\text{O}_7$ and an orthorhombic perovskite EuFeO_3

Pieces from sample No. 721 grown with 8 mm / h under flowing synthetic air under a high pressure of 9.2 - 9.7 bar. Powder x-ray diffraction indicates a multiphase material but most phases could not be identified. The amount of pyrochlore $\text{Eu}_2\text{Ti}_2\text{O}_7$ seems to be smaller than that in sample No. 720

In both cases no indications for a phase of the type $n = 6$ of $A_nB_nO_{3n+2}$

Prepared at the ETH Zurich in 2014

Stability limit of melt-grown $n = 6$ type $\text{Sm}_{6-y}\text{Eu}_y\text{Ti}_4\text{Fe}_2\text{O}_{20}$

The lanthanides Ln from La to Eu:

La	Ce	Pr	Nd	Pm	Sm	Eu
57	58	59	60	61	62	63

The results which are shown on the two previous pages indicate that the $n = 6$ stability limit $y = y_{\max}$ is located in the range $0.6 \leq y_{\max} < 6$

For comparison: The stability range of the $n = 4$ type ferroelectric insulators $Ln_4Ti_4O_{14} = Ln_2Ti_2O_7 = LnTiO_{3.5}$ ranges from $Ln = \text{La}$ to $Ln = \text{Nd}$. $\text{SmTiO}_{3.5}$ and $\text{EuTiO}_{3.5}$ crystallize in a cubic pyrochlore structure. However, the conducting material $\text{SmTiO}_{3.37}$ adopts a $n = 5$ type structure

It is provided via the link which is specified on page 2

Prepared at the ETH Zurich in 2016

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ $\text{Nb}^{5+} / 4d^0$ $\text{Fe}^{3+} / 3d^5$

Run / Sample No. 766

Fast mode video (~ 4 min) of the overall run (~ 4 h) in the Cyberstar mirror furnace. The video is only running in the ppsx type version of this publication, see page 2

The composition of the polycrystalline sintered rods is $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ and the floating zone melting is performed under flowing 90 % Ar + 10 % O_2

Lamp power to maintain the molten zone: 2×327 W

Speed of the lower shaft and seed rod (crystal growth speed): 14 mm / h

At the video time ~ 03 : 00 : 00 an exceptionally large gas-liquid region arises in the molten zone and persists for an unusually long time

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$

$\text{Nb}^{5+} / 4d^0$

$\text{Fe}^{3+} / 3d^5$

5 cm long as-grown crystalline material (1) plus polycrystalline seed rod (2)

Run or sample No. 766

Grown with 14 mm / h under 90 % Ar + 10 % O₂

Prepared at the ETH Zurich in 2016

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$

$\text{Nb}^{5+} / 4d^0$

$\text{Fe}^{3+} / 3d^5$

Crystalline pieces
from the as-grown
sample No. 766

Grown with
14 mm / h under
90 % Ar + 10 % O_2

Powder XRD:

Some peaks display
an unusual shape

4 unindexed peaks
with relative
intensity < 2 %

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ $\text{Nb}^{5+} / 4d^0$ $\text{Fe}^{3+} / 3d^5$

Run / Sample No. 777

Real time video (~ 1 min) of a short section of the overall run in the Cyberstar mirror furnace. The video is only running in the ppsx type version of this publication, see page 2

The composition of the polycrystalline sintered rods is $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ and the floating zone melting is performed under flowing 90 % Ar + 10 % O_2

Lamp power to maintain the molten zone: about 2×310 W

Speed of the lower shaft and seed rod (crystal growth speed): 12 mm / h

During this run the upper feed rod was not rotated

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$

$\text{Nb}^{5+} / 4d^0$

$\text{Fe}^{3+} / 3d^5$

Run / Sample 777

Visible within the quartz glass tube of the Cyberstar mirror furnace after the run:

- 3 Remaining part of the polycrystalline feed rod
- 2 As-grown crystalline material
- 1 Polycrystalline seed rod

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$

$\text{Nb}^{5+} / 4d^0$

$\text{Fe}^{3+} / 3d^5$

5 cm long as-grown crystalline material plus polycrystalline seed rod

Sample No. 777

Grown with 12 mm / h under 90 % Ar + 10 % O_2

Prepared at the ETH Zurich in 2016

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ $\text{Nb}^{5+} / 4d^0$ $\text{Fe}^{3+} / 3d^5$

Run / Sample No. 779

Fast mode video (~ 2 min) of the overall run (~ 5 h) in the Cyberstar mirror furnace. The video is only running in the ppsx type version of this publication, see page 2

The composition of the polycrystalline sintered rods is $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ and the floating zone melting is performed under flowing 90 % Ar + 10 % O_2

Lamp power to maintain the molten zone: 2×318 W

Speed of the lower shaft and seed rod (crystal growth speed): 6 mm / h

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$

$\text{Nb}^{5+} / 4d^0$

$\text{Fe}^{3+} / 3d^5$

25 mm long as-grown crystalline material plus polycrystalline seed rod

Run or sample No. 779

Grown with 6 mm / h under 90 % Ar + 10 % O_2

Prepared at the ETH Zurich in 2016

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$

$\text{Nb}^{5+} / 4d^0$

$\text{Fe}^{3+} / 3d^5$

Crystalline pieces from the
as-grown sample No. 779

Grown with 6 mm / h under
90 % Ar + 10 % O₂

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ $\text{Nb}^{5+} / 4d^0$ $\text{Fe}^{3+} / 3d^5$

Powder x-ray diffraction pattern of a pulverized crystalline piece of sample No. 779

Melt-grown $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ $\text{Nb}^{5+} / 4d^0$ $\text{Fe}^{3+} / 3d^5$

The magnetic moment $M(T)$ of a crystalline piece of sample No. 779 was measured by a SQUID magnetometer MPMS3. The magnetic field H was approximately oriented parallel to the layers. Shown is the plot of the inverse magnetic susceptibility $\chi(T)$

Ref. for data evaluation:
 Progress in
 Solid State
 Chemistry
36 (2008) 253

Inverse $\chi(T)$ of melt-grown $n = 6$ type $\text{La}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$ and $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$

No indication for long-range magnetic ordering in $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$ because the Fe content is probably too small for that. See also the two following pages ...

$\text{La}_6\text{Ti}_4\text{Fe}_2\text{O}_{20}$: Progress in Solid State Chemistry 36 (2008) 253 and Journal of Physics: Condensed Matter 25 (2013) 076003 • $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$: This work

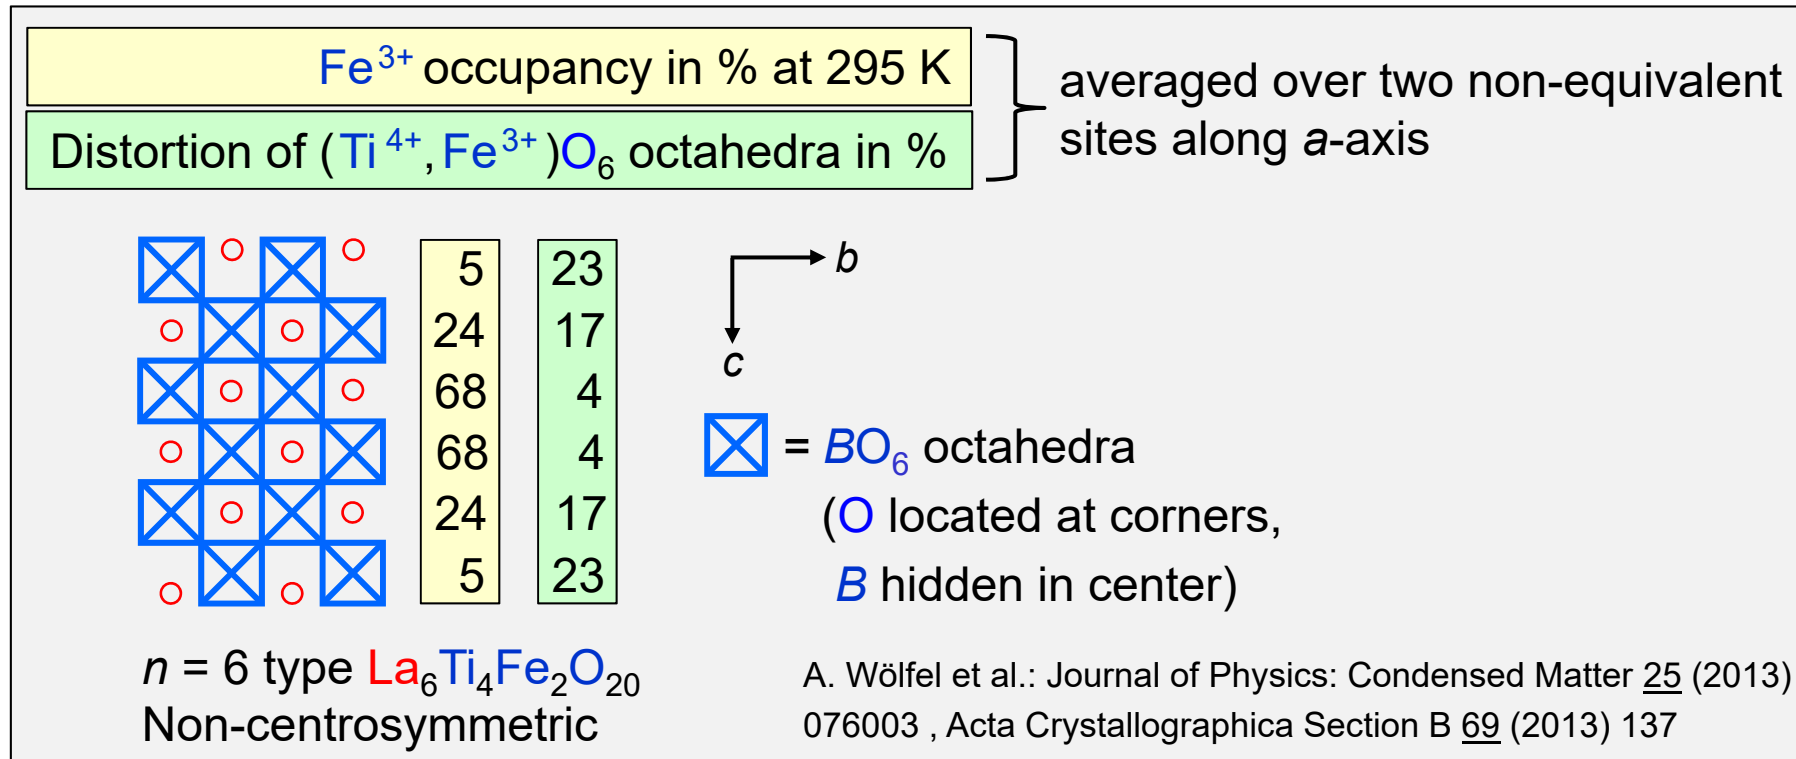

Melt-grown $n = 6$ type $Ln_6Ti_4Fe_2O_{20}$ and $Ca_6Nb_5FeO_{20}$

Some open questions

- Is it possible to synthesize a material with $B = (Ti, Fe)$ and a Fe³⁺ occupancy > 68 % at the central BO_6 octahedra ?
- Compared to Ti⁴⁺ and Fe³⁺ the both ions Nb⁵⁺ and Fe³⁺ have a larger difference of their valence. Does this imply for $Ca_6Nb_5FeO_{20}$ a sharper concentration gradient of Fe³⁺ and a larger Fe³⁺ occupancy at the central BO_6 octahedra ?

Melt-grown $n = 6$ type $Ln_6Ti_4Fe_2O_{20}$ and $Ca_6Nb_5FeO_{20}$

Some open questions

- Is $Ca_6Nb_5FeO_{20}$ non-centrosymmetric and polar or ferroelectric ?
- Is it possible to prepare a material of the type $A_6Nb_4Fe_2O_{20}$ with Nb^{5+} and Fe^{3+} ?
 It was already attempted to prepare melt-grown $n = 6$ type $Ca_4La_2Nb_4Fe_2O_{20}$ (run / sample No. 775). However, the melting and solidification behavior was difficult and the obtained melt-grown material is multiphase.

An unsuccessful attempt to prepare melt-grown $\text{Sr}_6\text{Nb}_5\text{FeO}_{20}$

Polycrystalline sintered rods with the composition $\text{Sr}_6\text{Nb}_5\text{FeO}_{20}$ (run / sample No. 772) were used for an attempt to prepare melt-grown $n = 6$ type $\text{Sr}_6\text{Nb}_5\text{FeO}_{20}$ which is potentially isostructural to the $n = 6$ type $\text{Ca}_6\text{Nb}_5\text{FeO}_{20}$. However, when processing the rods with the composition $\text{Sr}_6\text{Nb}_5\text{FeO}_{20}$ in the Cyberstar mirror furnace a very difficult melt and solidification behavior was observed. It indicated a strong deviation from congruent melting and solidification. The mirror furnace run was soon terminated because it was not possible to achieve a steady state of melting and solidification.

5.3 Materials in the context of potential multiferroic Carpy-Galy phases

5.3.3 Other known, hypothetical, and suggested compounds / systems ...

Already known: Multiferroic non-oxides $A_nB_nF_{3n+2}$ of the type $n = 2$

 = BF_6 octahedra (F located at the corners, B hidden in the center)

$n = 2$

- $n = 2$ type fluorine compounds $A_2B_2F_8 = ABF_4$ are known for $A = Ba$ and $B = Mg, Mn, Fe, Co, Ni$ or Zn

- B^{2+} : $Mn^{2+} / 3d^5$ $Fe^{2+} / 3d^6$ $Co^{2+} / 3d^7$
 $Ni^{2+} / 3d^8$ $Zn^{2+} / 3d^0$

- $B = Mn, Fe, Co$ or Ni :
 Antiferromagnetic (T_N about 20 - 70 K) and
 ferroelectric up to melting point (720 - 970 °C)

C. Ederer and N. Spaldin, Physical Review B 74 (2006) 024102

C. Ederer and N. Spaldin, Physical Review B 74 (2006) 020401 (R)

E. T. Keve et al., The Journal of Chemical Physics 51 (1969) 4928

Table 2 in Progress in Solid State Chemistry 29 (2001) 1

Hypothetical $n = 4$ type compounds

⊠ = BO_6 octahedra (O located at the corners, B hidden in the center)

$n = 4$

- Theoretical / computational study about ferroelectric $n = 4$ type $La_4Ti_4O_{14} = La_2Ti_2O_7$: Ab initio study of proper topological ferroelectricity in layered perovskite $La_2Ti_2O_7$, J. Lopez-Perez and J. Iniguez, Physical Review B 84 (2011) 075121
 - Significant polar character in structural distortions that are typically nonpolar
 - Observed proper ferroelectricity driven by O_6 rotations provides ideal conditions to obtain strong magnetoelectric effects
 - Strong magnetoelectric effects if the B site is occupied by magnetic ions such as $Mn^{4+} / 3d^3$ and hypothetical $n = 4$ type material $La_4Mn_4O_{14} = La_2Mn_2O_7$
- Potential $n = 4$ type thin films $Ln_2Ti_{2-w}Mn_wO_7$ ($w > 0$) on (110)-oriented $SrTiO_3$ with Ti^{4+} and Mn^{4+} are suggested: Zhenmian Shao, Sebastien Saitzek, Pascal Roussel, and Rachel Desfeux, Journal of Materials Chemistry 22 (2012) 24894

Hypothetical $n = 4$ type compounds

⊠ = BO_6 octahedra (O located at the corners, B hidden in the center)

$n = 4$

- Theoretical / computational study suggests multiferroicity in $n = 4$ type V-doped $La_2Ti_2O_7$, i.e. in $La_2Ti_{2-w}V_wO_7$ ($w > 0$): Marco Scarrozza, Alessio Filippetti, and Vincenzo Fiorentini, The European Physical Journal B 86 (2013) 128

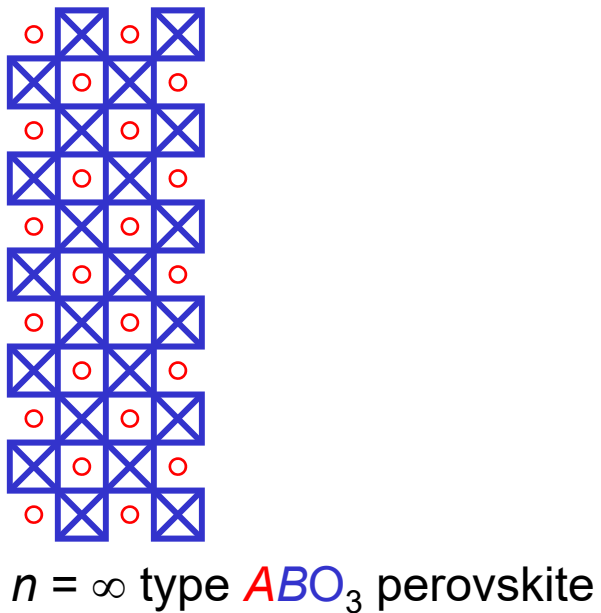

Estimation about the level of difficulty to synthesize the suggested materials

$La_2Mn_2O_7 \rightarrow$ Very difficult

$Ln_2Ti_{2-y}Mn_yO_7$ ($y > 0$) \rightarrow Increases with increasing y

$La_2Ti_{2-w}V_wO_7$ ($w > 0$) \rightarrow Relatively easy if w is not too large. An open question is the valence distribution among the Ti and V ions. Ti^{4+} and V^{4+} seems to be the most likely scenario

Suggested epitaxial (110)-oriented thin film hetrostructures 1 / 3

The following suggested hetrostructures are examples of a potential artificial extension of the (110)-oriented stacking of slabs or layers in the Carpy-Galy phases $A_n B_n O_{3n+2} = ABO_x \dots$

Suggested epitaxial (110)-oriented thin film heterostructures 2 / 3

Suggested $LaTiO_3 / LaTiO_{3.5}$ heterostructures

The $n = 4$ type $LaTiO_{3.5}$ is known as a high- T_c ferroelectric with $T_c = 1770$ K. The $n = \infty$ type perovskite $LaTiO_3$ is known as a weak ferromagnet / canted antiferromagnet with $T_N \approx 150$ K.

If it is possible to create epitaxial and (110)-oriented heterostructures which consist of thin films of ferroelectric $n = 4$ type $LaTiO_{3.5}$ and weak ferromagnetic $n = \infty$ type $LaTiO_3$, then the electric and magnetic properties / quantities are potentially coupled. If yes, then this represents potentially a novel magnetoelectric or multiferroic system.

(110)-oriented $n = 4$ type $LaTiO_{3.5}$

(110)-oriented $n = \infty$ type $LaTiO_3$

(110)-oriented $n = 4$ type $LaTiO_{3.5}$

(110)-oriented $n = \infty$ type $LaTiO_3$

substrate such as (110)-oriented $SrTiO_3$

Suggested epitaxial (110)-oriented thin film heterostructures 3 / 3

Suggested $LaFeO_3 / LaTiO_{3.5}$ heterostructures

The $n = 4$ type $LaTiO_{3.5}$ is known as a high- T_c ferroelectric with $T_c = 1770$ K. The $n = \infty$ type perovskite $LaFeO_3$ is known as a weak ferromagnet / canted antiferromagnet with $T_N \approx 740$ K.

If it is possible to create epitaxial and (110)-oriented heterostructures which consist of thin films of ferroelectric $n = 4$ type $LaTiO_{3.5}$ and weak ferromagnetic $n = \infty$ type $LaFeO_3$, then the electric and magnetic properties / quantities are potentially coupled. If yes, then this represents potentially a novel magnetoelectric or multiferroic system.

(110)-oriented $n = 4$ type $LaTiO_{3.5}$

(110)-oriented $n = \infty$ type $LaFeO_3$

(110)-oriented $n = 4$ type $LaTiO_{3.5}$

(110)-oriented $n = \infty$ type $LaFeO_3$

substrate such as (110)-oriented $SrTiO_3$

Another suggested system:

$n = \infty$ type LaTiO_3 micropillars in a ferroelectric $n = 4$ type $\text{LaTiO}_{3.5}$ matrix

Presented in part 8:
 $n = \infty$ type SrNbO_3
micro/nanopillars were
created by an electron beam
in a $n = 4$ type ferroelectric
 $\text{SrNbO}_{3.5}$ matrix

Image source: Tingting Yao et al., Nano Letters 20 (2020) 1047 - 1053
<https://doi.org/10.1021/acs.nanolett.9b04210>

The $n = \infty$ perovskite type LaTiO_3 is known as a weak ferromagnet / canted anti-ferromagnet with $T_N \approx 150$ K. The $n = 4$ type $\text{LaTiO}_{3.5}$ is known as a high- T_c ferroelectric with $T_c = 1770$ K. If it is possible to create weak ferromagnetic LaTiO_3 micropillars in a ferroelectric $\text{LaTiO}_{3.5}$ matrix, then the electric and magnetic properties / quantities are potentially coupled. If yes, then this represents a novel magnetoelectric system and potentially also a novel multiferroic system.

Sketch of a hypothetical system:
Weak ferromagnetic LaTiO_3 micropillars
in a ferroelectric $\text{LaTiO}_{3.5}$ matrix

Hypothetical materials related to the Schückel-Müller-Buschbaum phase

 = NbO₆ octahedra (O located at the corners, Nb hidden in the center)

 = NbO₄ (O located at the corners, Nb in the center)

Sketch of the crystal structure of the Schückel-Müller-Buschbaum phase

$\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16}$
 $= \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ which is related to the $n = 5$ type quasi-1D metal
 $\text{SrNbO}_{3.4} = \text{Sr}_5\text{Nb}_5\text{O}_{17}$
 $= \text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$

Presented in part 6.7 – 6.9 are

- the non-centrosymmetric and O-deficient $n = 5$ type Schückel-Müller-Buschbaum phase
 $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ in which the oxygen vacancies are fully ordered K. Schückel and Hk. Müller-Buschbaum, Zeitschrift für Anorganische und Allgemeine Chemie **528** (1985) 91
 F. Lichtenberg et al., Progress in Solid State Chemistry **36** (2008) 253
 S. C. Abrahams et al., Acta Crystallographica Section B **54** (1998) 399
- related Sr- and O-deficient $n = 5$ type electrical conductors such as $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$

Open question: Are there also related non-centrosymmetric insulators which are potentially ferroelectric, magnetoelectric, and / or multiferroic? It should be noted that compositions like $\text{SrNbO}_{3.2} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ and $A_{0.95}\text{BO}_{3.2} = A_{19}\text{B}_{20}\text{O}_{64}$ are close to that of the perovskite $\text{ABO}_3 = A_{20}\text{B}_{20}\text{O}_{60}$

The crystal structure of La_2RuO_5 in comparison to $n = 2$ of $A_nB_nO_{3n+2}$

As sketched on the following page
 La_2RuO_5 ($\text{Ru}^{4+} / 4d^4$) crystallizes in
a particular crystal structure which is
related to $n = 2$ of $A_nB_nO_{3n+2}$

La_2RuO_5 is a $m = 2$ member of a
hypothetical homologous series
 $A_{m+2}B_mO_{3m+4}$ and it is an open
question if other and also
non-centrosymmetric compounds
belonging to this series exist / can
be prepared. If yes, then there are
potentially novel magnetoelectric or
multiferroic materials among them.

The crystal structure of La_2RuO_5 in comparison to $n = 2$ of $\text{A}_n\text{B}_n\text{O}_{3n+2}$

 = BO_6 octahedra (O located at the corners, B hidden in the center)

La_2RuO_5 : Semiconductor-to-semiconductor transition and (antiferro?) magnetic ordering at $T \approx 160$ K, centrosymmetric

LaTaO_4 : Non-centrosymmetric as well as centrosymmetric modifications are reported

$n = 2$ of $\text{A}_n\text{B}_n\text{O}_{3n+2}$

$m = 2$ of hypothetical series $\text{A}_{m+2}\text{B}_m\text{O}_{3m+4}$

Open question: Are there other and also non-centrosymmetric compounds of the type

- Valence state study by electron energy-loss spectroscopy (EELS)
- Density functional theory (DFT) calculations by using atomic coordinates and structural data obtained from single crystal x-ray diffraction by P. Daniels et al., Acta Cryst. C 59 (2003) i15
- investigation of non-linear quantum transport by calculating the (electrical) transmission function of three devised Pt / $\text{La}_5\text{Ti}_5\text{O}_{17}$ / Pt systems along the a - , b - and c -axis

distortion of TiO_6 octahedra in percent

Z. Wang, L. Gu, M. Saito, S. Tsukimoto, M. Tsukada, F. Lichtenberg, Y. Ikuhara, and J. G. Bednorz, Advanced Materials 25 (2013) 218 • Octahedra distortions from Fig. 15 in Progress in Solid State Chemistry 36 (2008) 253

The $n = 5$ quasi-1D metal $\text{La}_5\text{Ti}_5\text{O}_{17}$ ($\text{Ti}^{3.8+}$, $3d^{0.2}$)

- Confinement of charge (delocalized 3d electrons) to the central octahedra / center of the layers or slabs
- Within unit cell metal-insulator-like interfaces which are similar to those in thin film heterostructures !
- DFT calculations indicate ferromagnetic ordering / spin-polarized quasi-1D electron gas. Experimentally not observed but the real material might be close to a state of itinerant ferromagnetism. Or computational artefact ?
- Assuming that one La sheet surrounding the central Ti is displaced down by 0.2 \AA as indicated by the black arrows \rightarrow DFT calculations result in a quasi-2D dispersion of valence bands around Fermi energy \rightarrow Quasi-1D metallic behavior is related to the overall structure and not only due to the presence of Ti – O chains along the a-axis !

A special feature of the $A_nB_nO_{3n+2} = ABO_x$ type quasi-1D metals

Structural, compositional and electronical proximity to (anti)ferroelectric insulators !

This distinguishes them from all other known quasi-1D metals such as $K_{0.3}MoO_3$, $Li_{0.9}Mo_6O_{17}$, $NbSe_3$, $(SN)_y$ and organic conductors like TTF-TCNQ

Examples:

$n = 4$: Ferroelectric $SrNbO_{3.5}$ ($4d^0$) \rightarrow Poor quasi-1D metal $Sr_{0.8}La_{0.2}NbO_{3.5}$ ($4d^{0.2}$)

$n = 5$: Antiferroelectric $SrNb_{0.8}Ti_{0.2}O_{3.4}$ ($4d^0$) \rightarrow Quasi-1D metal $SrNbO_{3.4}$ ($4d^{0.2}$)

Intrinsic coexistence of metallic conductivity and large dielectric polarizability in $A_nB_nO_{3n+2}$ type systems !?

Usually these both features exclude each other

Intrinsic coexistence of these both features might be useful for the creation of superconductors

The following experimental observations support the presence of such an intrinsic coexistence ...

Optical conductivity at $T = 300$ K along a - and b -axis of $n = 4$ ferroelectric insulator $\text{SrNbO}_{3.50}$ and weakly pronounced $n = 4$ quasi-1D metal $\text{Sr}_{0.8}\text{La}_{0.2}\text{NbO}_{3.50}$

▼ = Phonon peaks which survive in the conducting oxide

↓ = Ferroelectric soft mode (phonon peak associated with ferroelectric phase transition)

Ferroelectric soft mode peak occurs also in the weakly pronounced quasi-1D metal !

Magnetic susceptibility $\chi(T)$ of the ferroelectric insulator $\text{SrNbO}_{3.5}$ and quasi-1D metals of the type $(\text{Sr},\text{La})\text{NbO}_x$

Magnetic field
 $H \leq 1000 \text{ G}$
 parallel to
 the layers

Low
 temperature
 behavior is
 due to a
 Curie
 contribution
 C/T
 from para-
 magnetic
 impurities or
 defect states

Model considerations of $\chi(T)$ of the $n = 5$ type quasi-1D metal $\text{SrNbO}_{3.41}$

Bulk susceptibility $\chi(T)$ can be interpreted as arising from almost localized spins in a 1D Heisenberg chain with an exchange constant of $J = 530$ K

J.-E. Weber, C. Kegler, N. Büttgen, H.-A. Krug von Nidda, A. Loidl, and F. Lichtenberg, *Physical Review B* **64** (2001) 235414

Approach 1: Diamagnetic contribution from closed electron shells plus Curie-Weiss tail at low T from defect states plus Pauli paramagnetism from thermally activated charge carriers:

$$\chi(T) = \chi_{\text{dia}} + \frac{C}{T - \theta} + \chi_{\text{Pauli}} \exp\left(-\frac{E_g}{k_B T}\right)$$

Approach 2: Bonner-Fisher model of an 1D antiferromagnetic $S = 1/2$ Heisenberg spin chain for $T \geq 0.3 J$:

$$\begin{aligned} \chi_{1D}(T) &= \chi_{\text{dia}} + \frac{V\Gamma}{T} \\ &\times \frac{0.25 + 0.0774975J/T + 0.075235(J/T)^2}{1 + 0.9931J/T + 0.172135(J/T)^2 + 0.757825(J/T)^3} \end{aligned}$$

$50 \text{ K} \leq T \leq 400 \text{ K}$ and $J = 530 \text{ K}$

Examples of conducting materials which show another behavior of $\chi(T)$

For the $n = 4$ type $\text{LaTi}_{0.8}\text{Nb}_{0.2}\text{O}_{3.51}$, the $n = 4.5$ type $\text{LaTi}_{0.95}\text{Nb}_{0.05}\text{O}_{3.44}$, and the $n = 6$ type $\text{CaNb}_{0.8}\text{Ti}_{0.2}\text{O}_{3.33}$ the magnetic susceptibility $\chi(T)$ increases with decreasing temperature. These compounds are conducting but probably not metallic

6 Conducting and metallic Carpenter-Galy phases

6.2.1 Photoinduced properties of the quasi-1D metals

(Sr- and O-deficient $n = 5$) ...

Photoinduced properties of the quasi-1D metals $\text{SrNbO}_{3.45}$ ($n = 4.5$) and $\text{Sr}_{0.95}\text{NbO}_{3.37}$ (Sr- and O-deficient $n = 5$)

Photoinduced metastable exciton-driven metal-insulator transitions in quasi-one-dimensional transition metal oxides

to be published in Communications Physics (2020)

Abstract: Photoinduced phase transitions in matter have gained tremendous attention over the past few years. However, their ultrashort lifetime makes their study and possible control very challenging. Here, we report on new photoinduced metal-insulator transitions (MITs) in quasi-one-dimensional metals $\text{Sr}_{1-y}\text{NbO}_x$ using Mueller-Matrix spectroscopic ellipsometry, transient ultraviolet Raman spectroscopy, transient mid-infrared reflectivity and angular-resolved photoemission spectroscopy supported with density functional theory. The MITs are driven by photo-pumping of $d-d$ excitons, causing the metallic a -axis to become insulating while the insulating b - and c -axis concomitantly become a correlated metal. We assign these effects to the melting of charge and lattice orderings along the different anisotropic optical axes. The long lifetime in the order of several seconds of the metastable MITs gives a greater flexibility to study and manipulate the transient excitonic state. Fundamental questions associated with coherent excitonic states such as Bose-Einstein condensates and potential applications in exciton-based optoelectronic devices could now be addressed.

6 Conducting and metallic Carpenter-Gallagher phases

6.3 Why Carpenter-Gallagher phases

$A_n B_n O_{3n+2} = ABO_x$ might
have a potential to create
superconductors ...

Potential for high- T_c superconductivity in $A_nB_nO_{3n+2} = ABO_x$ quasi-1D metals from the perspective of so-called excitonic superconductivity

A hypothetical possibility to realize superconductivity at room temperature is given by the so-called excitonic mechanism of superconductivity (electron-electron mediated):

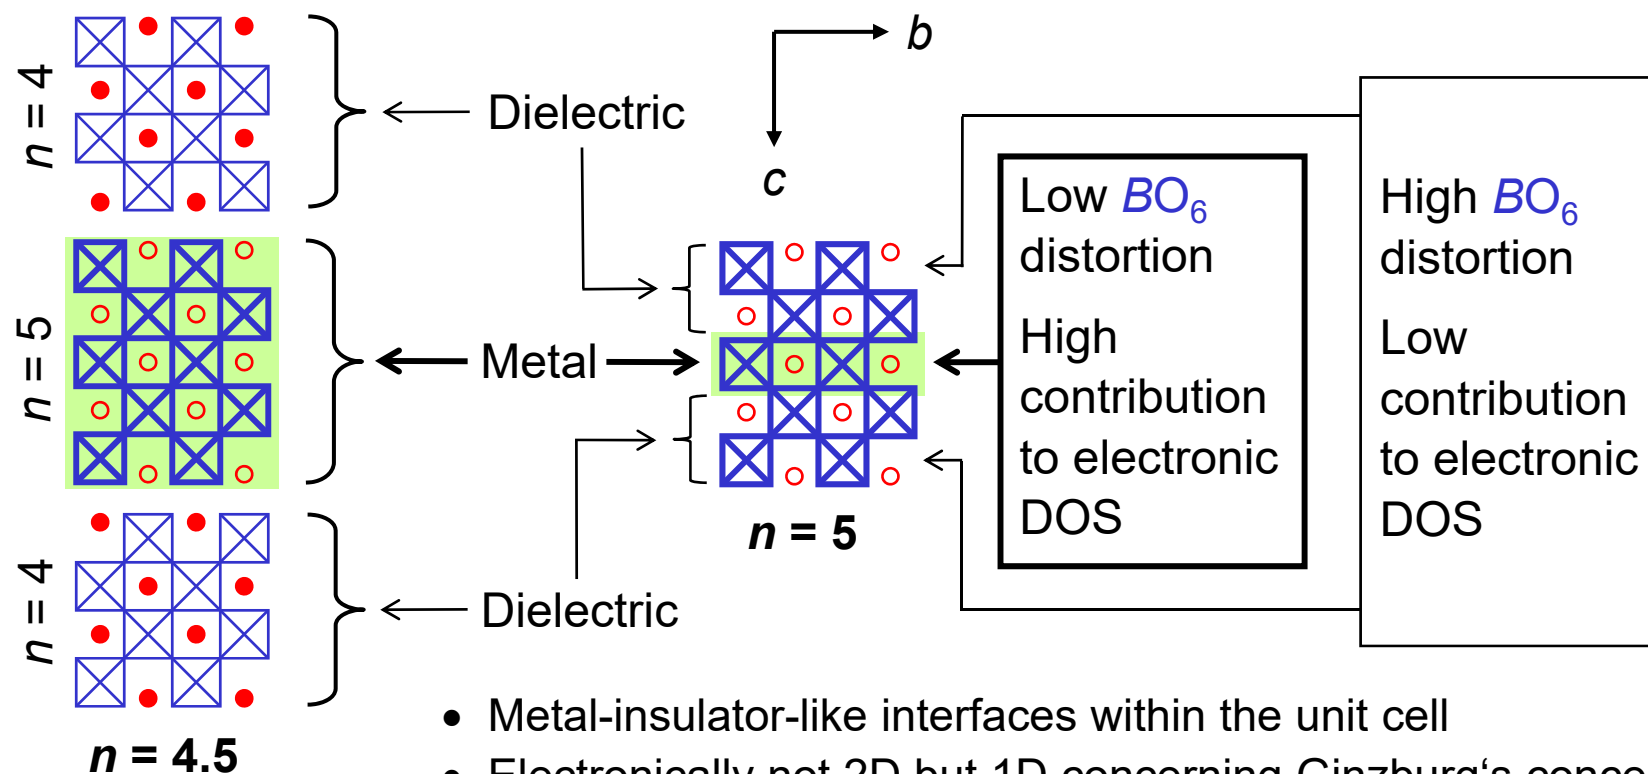

- Original proposal by W. A. Little for hypothetical **quasi-1D** organic conductors:
Conducting chains surrounded by electronically polarizable side branches
 - In: Novel Superconductivity, Plenum Press (1987) 341
 - Journal de Physique Colloque C3 Supplement No 6 (1983) 819
 - Int. Journal of Quantum Chemistry (Quantum Chemistry Symposium) 15 (1981) 545
 - Scientific American 212 (1965) 21
 - Physical Review 134 (1964) A1416
- Original proposal by V. L. Ginzburg for **quasi-2D** systems:
Thin metallic sheet surrounded by two dielectric layers
 - Soviet Physics Uspekhi 72 (1970) 335

The results of the studies on $La_5Ti_5O_{17} = LaTiO_{3.4}$ and $(Sr,La)NbO_x$, see part 6.1 and part 6.2, suggest the following scenario ...

Potential for high- T_c superconductivity in $A_nB_nO_{3n+2} = ABO_x$ quasi-1D metals from the perspective of so-called excitonic superconductivity

For example, the types $n = 4.5$ and $n = 5$ seem to be interesting from Little's and from Ginzburg's point of view:

- Quasi-2D crystal structure
- Electronically quasi-1D by $B - O$ chains and delocalized electrons along a -axis
- Electronically polarizable units by electronic band structure, fluctuating valence states of rare earth ions at A site ... ?

- Metal-insulator-like interfaces within the unit cell
- Electronically not 2D but 1D concerning Ginzburg's concept
- Also quasi-2D metals among $A_nB_nO_{3n+2}$ type oxides ?

Searching for high- T_c and ambient temperature superconductors

- Excitonic superconductivity only in a very small region of the compositional parameter space (W. A. Little, V. L. Ginzburg)
- “Therefore, synthesizing a room temperature superconductor, one must pay attention to its structure: the ”distance” between failure and success can be as small as 0.01 Å in the lattice constant”.

Synthesis approach:

$\text{WO}_{1.98}$ = Tungsten dioxide with thermogravimetrically determined oxygen content 1.98

Pre-reacted for 6 h at 600 °C under air. After mingling the pre-reacted material with $\text{WO}_{1.98}$ the obtained powder was pressed into a rectangular shape and heated and sintered for 6 h at 700 °C under argon in the GERO tube furnace.

A polycrystalline sintered $n = 5$ type composition $\text{NaWO}_{3.4}$

Sample No. 704 • Prepared at the ETH Zurich in 2012

Material is probably multiphase

Powder x-ray diffraction was not performed

The magnetic moment $M(T)$ and susceptibility $\chi(T)$ of a piece from this material was measured by a SQUID magnetometer in the temperature range $2 \text{ K} \leq T \leq 330 \text{ K}$.

$\chi(T)$ is weakly diamagnetic and nearly temperature-independent and no indication for superconductivity was detected.

Acknowledgement: F. L. thanks Bertram Batlogg (ETH Zurich) who performed the magnetic measurement with his Quantum Design SQUID Magnetometer MPMS XL

No indications for superconductivity in a polycrystalline sintered $n = 6$ type composition $\text{NaWO}_{3.33}$

Synthesis approach analogous to what is described on the previous page but with another appropriate ratio $\text{WO}_3 / \text{WO}_{1.98}$

Two as-pressed rods with composition $\text{NaWO}_{3.33}$

Rods with composition $\text{NaWO}_{3.33}$ after they were heated and sintered under argon

Run / Sample No. 711 • Prepared at the ETH Zurich in 2013

Material is probably multiphase • Powder x-ray diffraction was not performed

Processing the sintered rods by floating zone melting did not work because of a difficult melting behavior and strong bending of the seed rod in the mirror furnace

The magnetic moment $M(T)$ of a piece from the sintered rods was measured by a SQUID magnetometer in the temperature range $2 \text{ K} \leq T \leq 300 \text{ K}$ and no indication for superconductivity was detected. **Acknowledgement:** F. L. thanks Marisa Medarde (PSI) and Mickael Morin (PSI) for performing a magnetic measurement with a Quantum Design SQUID magnetometer MPMS XL and Nicholas Bingham (PSI) for performing a magnetic measurement with a Quantum Design SQUID magnetometer MPMS3

A hypothetical $n = 5$ type material which is potentially a ferroelectric metal: $\text{Bi}_5\text{Ti}_5\text{O}_{17}$

Prediction of a native ferroelectric metal

Alessio Filippetti, Vincenzo Fiorentini, Francesco Ricci, Pietro Delugas & Jorge Iniguez

Nature Communications 7 (2016) 11211 (1 - 7)

<https://doi.org/10.1038/ncomms11211>

To the best of our knowledge there is so far no publication about the synthesis of $\text{Bi}_5\text{Ti}_5\text{O}_{17}$. It is probably very difficult to prepare, if at all possible

Abstract

Over 50 years ago, Anderson and Blount discussed symmetry-allowed polar distortions in metals, spawning the idea that a material might be simultaneously metallic and ferroelectric. While many studies have ever since considered such or similar situations, actual ferroelectricity - that is, the existence of a switchable intrinsic electric polarization - has not yet been attained in a metal, and is in fact generally deemed incompatible with the screening by mobile conduction charges. Here we refute this common wisdom and show, by means of first-principles simulations, that native metallicity and ferroelectricity coexist in the layered perovskite $\text{Bi}_5\text{Ti}_5\text{O}_{17}$. We show that, despite being a metal, $\text{Bi}_5\text{Ti}_5\text{O}_{17}$ can sustain a sizable potential drop along the polar direction, as needed to reverse its polarization by an external bias. We also reveal striking behaviours, as the self-screening mechanism at work in thin $\text{Bi}_5\text{Ti}_5\text{O}_{17}$ layers, emerging from the interplay between polar distortions and carriers in this compound.

Another potential polar or ferroelectric metals

$\text{SrNbO}_{3.4} = \text{Sr}_5\text{Nb}_5\text{O}_{17} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$ is a centrosymmetric $n = 5$ type quasi-1D metal which is described in part 6.2 and 6.5 – 6.7

There is a related O-deficient $n = 5$ type niobate, namely the non-centrosymmetric Schücker-Müller-Buschbaum phase

which is presented in part 6.7 . Its physical properties are not yet known. If the non-centrosymmetric $\text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ is a quasi-1D metal, then it is potentially a polar or ferroelectric metal.

Melt-grown Schücker-Müller-Buschbaum type phases, namely the Sr- and O-deficient $n = 5$ type $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ and $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$, are presented in part 6.9.1 and 6.9.5 – 6.9.8 . If they are likewise non-centrosymmetric and if they are quasi-1D metals, then they are potentially polar or ferroelectric metals.

Results of angle-resolved photoemission spectroscopy (ARPES) on crystals of melt-grown $n = 4.5$ type $\text{SrNbO}_{3.45}$ published in 1997

ARPES probes the occupied electronic states and their dispersion $E(k)$, $k = k(\theta)$

A band with dispersion, i.e. $E(k) \neq \text{constant}$, was detected only along the a -axis

This result which was published by D. H. Lu et al. in 1997 was the first indication that the $n = 4.5$ type $\text{SrNbO}_{3.45}$ could be a quasi-1D metal

D. H. Lu, C. S. Gopinath, M. Schmidt, T. R. Cummins, N. Nücker, S. Schuppler, and F. Lichtenberg, *Physica C* **282 - 287** (1997) 995

Subsequently this and other $A_n B_n O_{3n+2} = ABO_x$ type niobates and titanates were comprehensively studied by optical spectroscopy and ARPES by C. A. Kuntscher et al. and by resistivity measurements with special electrical voltage contacts by F. Lichtenberg et al. As presented in part 6.1 and 6.2 the corresponding results clearly show that many of the studied materials are quasi-1D metals.

The result by D. H. Lu et al. triggered some attempts to detect the quasi-1D metallic behavior also in resistivity measurements by using improved or special electrical voltage contacts ...

Electrical contacts for resistivity measurements on crystals

After the ARPES results from D. H. Lu et al. on $n = 4.5$ type $\text{SrNbO}_{3.45}$ it was attempted to detect the quasi-1D metallic behavior also in temperature-dependent resistivity measurements. When compared to the former approach whose results were published in 1991 two modifications were implemented :

- Laue diffraction was used to determine the orientation of the crystals and in-plane current and voltage contacts along the a - and b -axis were attached
- Some attempts of using different types of in-plane voltage contacts resulted in the conclusion that only ultrasonically bonded wires lead to the detection of a metallic resistivity behavior along the a -axis

Sketch of the arrangement of electrical contacts for resistivity measurements in a four-point configuration on a rectangular plate-like crystal along the a -, b - and c -axis. V and I denote the voltage and current contacts, respectively

Electrical contacts for resistivity measurements on crystals

A crystal prepared for four-point resistivity measurements along two different directions within the ab -plane, usually along the a - and b -axis. The size of this crystal is $(1.7 \text{ mm}) \times (1.7 \text{ mm}) \times (0.3 \text{ mm})$. At the four sides the current leads, $50 \mu\text{m}$ diameter Au wires, are attached with silver paint. On the top there are six voltage contacts, $25 \mu\text{m}$ diameter Al wires, which were mechanically fixed by ultrasonic bonding. Although one current direction requires only two voltage contacts, the presence of more contacts can be very useful, e.g. if one of them fails.

The same crystal as shown above but now with contacts for a four-point resistivity measurement perpendicular to the layers. Shown is one of the both sides with two contacts which were prepared by silver paint and $50 \mu\text{m}$ diameter Au wires. The U-like shape is used as current contact and the other in the middle as voltage contact. There are two corresponding contacts on the other side of the crystal.

Examples of results of resistivity measurements on plate-like crystals with ultrasonically bonded in-plane voltage contacts published in 2001

 Progress in Solid State Chemistry 29 (2001) 1

Types of electrical in-plane voltage contacts for resistivity measurements on crystals

It is an open question why in-plane voltage contacts made of thin wires and silver paint are not able to detect the metallic resistivity behavior along the a -axis

- In contrast to silver paint voltage contacts, which are just attached on the surface of the crystal, ultrasonically bonded voltage contacts penetrate somewhat into the surface of the crystal
- A. Moini et al. reports that initial measurements on crystals of structurally and electronically low-dimensional $\text{La}_2\text{Mo}_2\text{O}_7$ with silver paste contacts lead to erratic results, but the problem was solved by ultrasonically soldered indium contacts

Journal of Solid State Chemistry 66 (1987) 136

Note: The crystal structure of $\text{La}_2\text{Mo}_2\text{O}_7$ is not of the type $A_nB_nO_{3n+2}$

Results of resistivity measurements on crystals of melt-grown $n = 5$ type $\text{SrNb}_{0.964}\text{O}_{3.41-y}$ published by A. de Campos et al. in 2010

Reference and image source: Physical properties of quasi-one-dimensional $\text{SrNbO}_{3.41}$ and Luttinger liquid analysis of electrical transport • A. de Campos, M. S. da Luz, C. A. M. dos Santos, A. T. Rice, A. M. Deml, B. D. White, J. J. Neumeier, and J. L. Cohn • Physical Review B 82 (2010) 125117
<http://dx.doi.org/10.1103/PhysRevB.82.125117>

Melt-grown Nb- and O-deficient $n = 5$ type $\text{SrNb}_{0.964}\text{O}_{3.41-y}$ was prepared by sintering polycrystalline rods with fully oxidized Nb^{5+} composition $\text{SrNb}_{0.964}\text{O}_{3.41}$ under 97 % Ar + 3 % H_2 followed by processing the sintered rods by floating zone melting under 97 % Ar + 3 % H_2 with a gas flow rate of 72 L / h. The growth speed was 5 mm / h. The oxygen content $x = 3.41 - y$ is not specified but a single phase $n = 5$ type material was confirmed by x-ray-diffraction. The electrical resistance and resistivity was determined by the Montgomery method with low-resistance vapor-deposited gold contacts as well as by the four-point method.

Results of resistivity measurements on crystals of melt-grown $n = 5$ type $\text{SrNb}_{0.964}\text{O}_{3.41-y}$ published by A. de Campos et al. in 2010

The Montgomery method may provide a better assessment of the resistivity behavior than the four-point method because the latter may comprise an intermixture of resistivity contributions from different directions or crystallographic axes.

The diagonal components of the electrical resistivity tensor of $\text{SrNb}_{0.964}\text{O}_{3.41-y}$ were determined by the Montgomery method. The results confirm a quasi-1D behavior with a smaller anisotropy than previously reported by F. Lichtenberg et al. in 2001 on crystals of melt-grown $n = 5$ type $\text{SrNbO}_{3.41}$

Reference: Physical properties of quasi-one-dimensional $\text{SrNbO}_{3.41}$ and Luttinger liquid analysis of electrical transport • A. de Campos, M. S. da Luz, C. A. M. dos Santos, A. T. Rice, A. M. Deml, B. D. White, J. J. Neumeier, and J. L. Cohn

• Physical Review B 82 (2010) 125117 • <http://dx.doi.org/10.1103/PhysRevB.82.125117>

Note: The composition of the melt-grown $n = 5$ type $\text{SrNb}_{0.964}\text{O}_{3.41-y}$ (y not specified) and the melt-grown $n = 5$ type $\text{SrNbO}_{3.41}$ ($\text{Nb}^{4.82+} / 4\text{d}^{0.18}$) is not the same. That could be also a reason why the resistivity behavior and anisotropy of these both materials are (somewhat) different.

Results of resistivity measurements on crystals of melt-grown $n = 5$ type $\text{SrNbO}_{3.43}$ published by W. Kobayashi et al. in 2011 – Electrical contacts made with silver paint

Melt-grown $n = 5$ type $\text{SrNbO}_{3.43}$ was prepared by processing polycrystalline sintered rods with fully oxidized Nb^{5+} composition $\text{SrNbO}_{3.5}$ by floating zone melting under 97 % Ar + 3 % H_2 with a gas flow rate of 12 L / h. The growth speed was 10 mm / h. The oxygen content $x = 3.5 - y = 3.43$ was determined thermogravimetrically. A single phase $n = 5$ type material was confirmed by synchrotron powder x-ray-diffraction measurements. The specified orthorhombic lattice parameters are $a = 3.988 \text{ \AA}$, $b = 5.676 \text{ \AA}$, and $c = 32.467 \text{ \AA}$. The electrical resistivity was measured by the four-point method and gold wires which were attached on the crystal by silver paint.

Paper in German but title and abstract also in English

Title: About a Mixed Valence Oxoniobate: $\text{Sr}_5\text{Nb}_3^{4+}\text{Nb}_2^{5+}\text{O}_{16}$

Abstract: The hitherto unknown compound $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ was prepared and examined by X-ray single crystal work. It crystallizes with orthorhombic symmetry (space group $D_{2h}^7 - \text{Pmn}2_1$, $a = 3.992(1)$, $b = 5.677(2)$, $c = 32.476(10)$, $Z = 2$). $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ consists of stacked perovskite-like blocks cut by a plane perpendicular to the cube face diagonal of the perovskite structure. The coordination relations of the intersections between those blocks and the distribution of Nb^{5+} and Nb^{4+} are discussed. Compared to the original text b and c are swapped so that they correspond to the assignment used in this work

In this work we suggest and introduce for $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ and its reported crystal structure the name Schückel-Müller-Buschbaum phase.

The Schückel-Müller-Buschbaum phase $\text{Sr}_5\text{Nb}_5\text{O}_{16}$

In 1985 K. Schückel and Hk. Müller-Buschbaum have published the following paper about the synthesis of $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ and its structure determination by single crystal x-ray diffraction:

Paper in German but title and abstract also in English

Synthesis and analysis (translated from German into English): Mingled 2 SrO + Nb₂O₅ was pressed into a disk. On it a layer of Nb metal powder was pressed. The disk which consisted of an oxide layer and a metal layer was heated in a H₂ / H plasma at about 2000 °C (surface temperature) for 30 minutes. The H₂ / H plasma was generated by a low pressure and high frequency plasma torch. The metal powder layer couples to the high frequency field and intensifies at the oxide / metal interface the effect of the plasma torch. The reaction takes place at the 2 SrO + Nb₂O₅ / Nb interface where small blue-gray crystals did arise. The Sr and Nb content of the crystals was determined by energy dispersive x-ray spectroscopy (EDX). The oxygen content could only be determined with a complete structure analysis by single crystal x-ray diffraction.

The Schücker-Müller-Buschbaum phase $\text{Sr}_5\text{Nb}_5\text{O}_{16}$

In 1985 K. Schücker and Hk. Müller-Buschbaum have published the following paper about the synthesis of $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ and its structure determination by single crystal x-ray diffraction:

Ein weiteres gemischtvalentes Oxoniobat: $\text{Sr}_5\text{Nb}_3^{4+}\text{Nb}_2^{5+}\text{O}_{16}$

K. Schücker and Hk. Müller-Buschbaum

Zeitschrift für anorganische und allgemeine Chemie 528 (1985) 91 - 97

<https://doi.org/10.1002/zaac.19855280909>

Paper in German but title and abstract also in English

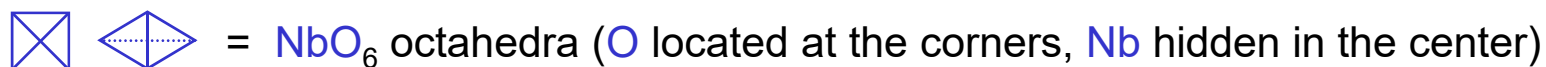

Notes

- Physical properties are not reported / were not studied
- Oxides of the type $A_nB_nO_{3n+2}$ and a relationship to the structure type $n = 5$ are not mentioned

The mixed valence and conducting niobates $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ and $\text{Sr}_5\text{Nb}_5\text{O}_{17}$

Composition		$\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16}$ $= \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$	$\text{SrNbO}_{3.4} = \text{Sr}_5\text{Nb}_5\text{O}_{17}$ $= \text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$
Synthesis approach		2 SrO + Nb ₂ O ₅ with Nb on surface was heated in a H ₂ / H plasma → Small crystals. Synthesis via melt did not work (incongruent melting)	Floating zone melting of the composition Sr ₅ Nb ₅ O ₁₇ under Ar
Structure type		Schückel-Müller-Buschbaum phase Oxygen-deficient n = 5 type with fully ordered oxygen vacancies	n = 5 type Carpy-Galy phase $\text{ABO}_x = \text{A}_n\text{B}_n\text{O}_{3n+2}$

unfavorable ?

NbO_4 polyhedra
with Nb^{5+} ?

The Schücker-Müller-Buschbaum phase $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16}$

Comments and open questions

- In contrast to the quasi-1D metal $\text{Sr}_5\text{Nb}_5\text{O}_{17}$ a layer or slab of $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ comprises along the *c*-axis an asymmetric distribution of the Nb^{4+} ($4d^1$) and Nb^{5+} ($4d^0$) ions and Nb – O polyhedra distortions. Maybe these particular details of the $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ type structure can bring forth special physical properties
- What are its physical properties ?
 - Is it a quasi-1D metal like the related $n = 5$ type $\text{SrNbO}_{3.4} = \text{Sr}_5\text{Nb}_5\text{O}_{17}$?
If yes, is $\text{Sr}_5\text{Nb}_5\text{O}_{16}$ because of its non-centrosymmetric structure a polar or ferroelectric metal ?
- Are there related materials which can be prepared via the melt ?
 - If yes, then larger amounts of crystalline material / larger crystals could be obtained. That would facilitate the study of the physical properties
 - Can the crystal structure reported by K. Schücker and Hk. Müller-Buschbaum be confirmed ?

The Schücker-Müller-Buschbaum phase $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16}$

Comments and open questions

- Its reported crystal structure can be considered as an oxygen-deficient $n = 5$ type structure with fully ordered oxygen vacancies. Therefore the Schücker-Müller-Buschbaum phase and potential related compounds with the same type of crystal structure, i.e. Schücker-Müller-Buschbaum type phases, represent a special subset of the Carpy-Galy phases $A_nB_nO_{3n+2} = ABO_x$
- The oxygen-deficient $n = 5$ type structure of $\text{SrNbO}_{3.2}$ is perovskite-related and layered and its composition is close to that of the non-layered $n = \infty$ type perovskite SrNbO_3

For comparison: In the system LaTiO_x the $n = \infty$ type perovskite structure has a large homogeneity range, namely $3.00 \leq x \leq 3.20$, i.e. it extends up to the composition $\text{LaTiO}_{3.2}$ (see part 6.1)

The Schücker-Müller-Buschbaum phase $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16}$

Comments and open questions

- The overall homogeneity range of $n = 5$ type SrNbO_x seems to be $3.20 \leq x \leq 3.42$ whereby $x = 3.40$ corresponds to the stoichiometric composition
- When having prepared a series of niobates SrNbO_x with an oxygen content ranging from $x = 3.40$ to $x = 3.20$: Is there a specific oxygen content x_c or a two-phase oxygen content range which separates the two single phases
 - centrosymmetric / non-centrosymmetric
 - symmetric / asymmetric distribution of the Nb^{4+} and Nb^{5+} ions
 - symmetric / asymmetric distribution of the Nb – O polyhedra distortions ?
- For $x \approx 3.33$ basically an $n = 6$ type phase could arise but for SrNbO_x there are no indications for that. An example for an $n = 6$ type material is the ferroelectric insulator $\text{SrNb}_{0.67}\text{Ti}_{0.33}\text{O}_{3.33}$ ($\text{Nb}^{5+} / 4d^0$ and $\text{Ti}^{4+} / 3d^0$)

6 Conducting and metallic Carpy-Galy

Melt-grown synthesis under a high gas pressure of about 9.5 bar

Synthesis approach

$$s + c + b = 1$$

Pre-reaction at elevated temperatures under air

Melt and solidify polycrystalline sintered rods
with fully oxidized composition $(\text{Sr, Ca, Ba})_{19}\text{Nb}_{19}\text{WO}_{69.5}$
under an argon-hydrogen atmosphere

Melt-grown crystalline material with reduced composition

Its oxygen content $x = 69.5 - y$ can be determined by thermogravimetric oxidation towards the fully oxidized $x = x_F = 69.5$. Fully oxidized composition means that all Nb and W ions are in their highest valence state 5+ and 6+, respectively

The valence or oxidation state of the W ions in melt-grown reduced $(\text{Sr}, \text{Ca}, \text{Ba})_{19}\text{Nb}_{19}\text{WO}_{69.5 - y}$

When comparing a W-free composition ... Nb_{20} ... with a corresponding W-containing composition ... Nb_{19}W ... then the presence of W results in a significantly enhanced degree of reduction, i.e. $y(\text{Nb}_{19}\text{W}) > y(\text{Nb}_{20})$

To the best of our knowledge $\text{W}^{4+} / 5d^2$ is the lowest valence or oxidation state of W in oxides and $\text{W}^{6+} / 5d^0$ can be reduced easier than $\text{Nb}^{5+} / 4d^0$

Therefore the most likely scenario seems to be $\text{W}^{4+} / 5d^2$

Starting materials (powder) and preparation of sintered rods

Starting material	Supplier	Lot or Ch. No.	Purity (%) metals basis if not otherwise specified	Before using the powder it was heated under air at ... (°C) and subsequently stored in a desiccator	Calculated amount (g) for run / sample No. 838
SrCO ₃	ChemPur	150916	99.994	250	4.1828
CaCO ₃	ChemPur	120717	99.9	250	0.1668
BaCO ₃	ChemPur	050514	99.999	250	0.3289
Nb ₂ O ₅	Alfa Aesar	W10A029	99.9	400	4.2087
WO ₃	Alfa Aesar	10183650	99.998 excluding Mo Mo 100 ppm	400	0.3864

The starting materials were mingled by an agate mortar and pestle and then pre-reacted for 4 h at a temperature around 1200 °C under air in an alumina crucible which was placed into a laboratory chamber furnace Linn High Therm VMK 1600. Afterwards the pre-reacted and somewhat sintered powder mixture was grinded into powder which was mingled by an agate mortar and pestle. Subsequently a part of the pre-reacted powder was pressed into the shape of two rectangular rods by using special pressing dies made of magnesia-stabilized zirconia. Then the as-pressed rods were sintered under air.

6 Conducting and metallic Carpy-Galy
phases $A_n B_n O_{3n+2} = ABO_x$

6.9.2 Towards a Schückerl-Müller-Buschbaum
type phase: Synthesis and properties of
 $Sr_{19}Nb_{19}WO_{66} \dots$

Polycrystalline sintered rods with fully oxidized composition $\text{Sr}_{19}\text{Nb}_{19}\text{WO}_{69.5}$, i.e. all Nb and W ions are in their highest valence or oxidation state Nb^{5+} and W^{6+} , respectively

The as-pressed rods were 4 h sintered at 1280 °C under air. The sintering did result in a shrinkage of their length, namely $\Delta L \approx - 6$ mm for the long rod and $\Delta L \approx - 3$ mm for the short rod

Magnetic measurements

After magnetic measurements by a SQUID magnetometer the electrical resistance R of a part of this piece, called 814 C4 R, was measured by a multimeter
→ $R \geq 10 \Omega$

Crystalline piece C4-1 from section C4

This piece with a mass $m = 187 \text{ mg}$ was used to study its magnetic properties by a SQUID magnetometer

812 C4 $\text{Sr}_{19}\text{Nb}_{19}\text{WO}_{66}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

6.9 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

812 C4 $\text{Sr}_{19}\text{Nb}_{19}\text{WO}_{66}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

6.9 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

The behavior of $\chi(T)$ in the range from 390 K to 100 K is similar to that of $A_nB_nO_{3n+2}$ type quasi-1D metals. Thus this $n = 5$ type material is potentially also a quasi-1D metal

812 C4 $\text{Sr}_{19}\text{Nb}_{19}\text{WO}_{66}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

6.9 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

Increase of $\chi(T)$ below 90 K probably not due to paramagnetic impurities or defect states because they give usually a signal only at lower temperatures. Increase below 90 K due to 5d electrons which become localized ?

812 C4 $\text{Sr}_{19}\text{Nb}_{19}\text{WO}_{66}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

6.9 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

D = diamagnetic contribution from closed electron shells of Sr^{2+} , Nb^{5+} , W^{6+} , and O^{2-}

6.9.3 Towards a Schückerl-Müller-Buschbaum
type phase: Synthesis and properties of
 $Sr_{17}CaBaNb_{19}WO_{65.5} \dots$

As-pressed rods with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 828

As-pressed rods in an alumina box. Ready for sintering under air. The as-pressed rods are located on a lower punch which is made of yttria-stabilized zirconia. The length of the long rod is 9 cm

Both as-pressed rods have the fully oxidized composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$, i.e. all Nb and W ions are in their highest valence or oxidation state Nb^{5+} and W^{6+} , respectively

Sintered rods with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 828

A somewhat lower sintering temperature would have been better because the sintered rods were attached on their lower punch. Fortunately it was possible to remove the rods from their lower punch without damaging the rods. Later related experiments revealed that lower punches made of alumina are more suitable

The as-pressed rods were 4 h sintered at 1240 °C under air. The sintering did result in a shrinkage of their length, namely $\Delta L \approx - 5$ mm for the long rod and $\Delta L \approx - 2.5$ mm for the short rod

This piece was used to study its magnetic
properties by a SQUID magnetometer

828 C4 $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{65.5}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

8.1 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

828 C4 $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{65.5}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

8.1 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

The behavior of $\chi(T)$ in the range from 390 K to 105 K is similar to that of $A_nB_nO_{3n+2}$ type quasi-1D metals. Thus this $n = 5$ type material is potentially also a quasi-1D metal

828 C4 $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{65.5}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

8.1 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

Increase of $\chi(T)$ below 95 K probably not due to paramagnetic impurities or defect states because they give usually a signal only at lower temperatures. Increase below 95 K due to 5d electrons which become localized ?

828 C4 Sr₁₇CaBaNb₁₉WO_{65.5} Magnetic susceptibility $\chi(T)$

DC magnetic moment M(T) measured by a Quantum Design SQUID magnetometer MPMS3

8.1 d-electrons from Nb⁴⁺ / 4d¹ and W⁴⁺ / 5d²

D = diamagnetic contribution from closed electron shells of Sr²⁺, Ca²⁺, Ba²⁺, Nb⁵⁺, W⁶⁺, and O²⁻

6.9.4 Towards a Schückel-Müller-Buschbaum
type phase: Synthesis and properties of
 $Sr_{17}CaBaNb_{19}WO_{65.3} \dots$

**Melt-grown synthesis of $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5 - y}$
under a gas pressure of about 9.5 bar**

Run No. 836

Intention of this run

In the previous part 6.9.3 the run / sample No. 828 is presented. It describes the melt-grown synthesis of $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{65.45}$ which was prepared by reducing the fully oxidized composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$ under flowing 97.2 % Ar + 2.8 % H_2 with an ambient or normal gas pressure.

The intention of this run No. 836 was to repeat run No. 828 with only one difference, namely using instead of a normal gas pressure a high gas pressure of about 9.5 bar. The enhanced gas pressure results in a higher melting point which implies usually a higher degree of the reduction. This was indeed confirmed by the thermogravimetrically determined oxygen content $x = 69.5 - y$. However, the increased degree of reduction was smaller than anticipated so that a desired oxygen content of $x \approx 64$ could not be obtained in this way.

As-pressed rod with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 836

As-pressed feed rod in an alumina box. Ready for sintering under air. The as-pressed rod is located on a lower punch which is made of yttria-stabilized zirconia. The length of the rod is 9 cm

As-pressed feed rod with fully oxidized composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$, i.e. all Nb and W ions are in their highest valence or oxidation state Nb^{5+} and W^{6+} , respectively. A second rod, the seed rod, was not prepared because the remaining seed rod from run No. 828 was used in this run

Sintered rod with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 836

The as-pressed feed rod was 4 h sintered at 1230 °C under air. The sintering did result in a shrinkage of its length, namely $\Delta L \approx - 3 \text{ mm}$

A somewhat lower sintering temperature would have been better because the sintered rod was attached on its lower punch. Fortunately it was possible to remove the rod from its lower punch without damaging the rod. Later related experiments revealed that lower punches made of alumina are more suitable

Sintered rod with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 836

A second rod, the seed rod, was not prepared because the remaining seed rod from run No. 828 was used in this run

Melt-grown synthesis of $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5-y}$ under a gas pressure of about 9.5 bar

Starting materials for the mirror furnace run: Polycrystalline sintered rods with fully oxidized composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Fast mode video from the overall melt-grown synthesis of $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5-y}$ under ≈ 9.5 bar 97.2 % Ar + 2.8 % H_2 in the Cyberstar mirror furnace. The video is only running in the ppsx type version of this publication, see page 2

Gas flow rate: 400 sccm (24 L / h)

Gas type setting at the mass flow controller: Ar

Lamp power to maintain the molten zone: $2 \times (480 - 460)$ W

Speed of the lower shaft and seed rod (crystal growth speed): 14 mm / h

Melt-grown synthesis of $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5-y}$ under a gas pressure of about 9.5 bar

6.9.5 A Schückel-Müller-Buschbaum type
phase: Synthesis and properties of
 $Sr_{17}CaBaNb_{19}WO_{64} \dots$

Melt-grown synthesis of $(\text{Sr,Ca,Ba})_{19}\text{Nb}_{19}\text{WO}_{69.5-y}$ under 95 % Ar + 5 % H_2
Run / sample No. 838 (this part 6.9.5) and 826 (part 6.9.6)

In the previous part 6.9.4 , 6.9.3 , and 6.9.2 the run / sample No. 836 , 828 , and 812 is presented, respectively. It describes the melt-grown synthesis of materials $(\text{Sr,Ca,Ba})_{19}\text{Nb}_{19}\text{WO}_{69.5-y}$ which were prepared by reducing the fully oxidized composition $(\text{Sr,Ca,Ba})_{19}\text{Nb}_{19}\text{WO}_{69.5}$ under flowing 97.2 % Ar + 2.8 % H_2

This part 6.9.5 and the following part 6.9.6 present the results of attempts to achieve a higher degree of reduction by using a flowing argon-hydrogen atmosphere with a higher hydrogen content, namely 5 % H_2 instead of 2.8 % H_2 . In this way it was possible to synthesize materials with an oxygen content of $x = 69.5 - y = 64$

Powder with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 838

Powder with fully oxidized composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$ in an agate mortar. This powder was prepared by heating the mingled starting materials for 4 h at 1190 °C under air. Subsequently the somewhat sintered material was grinded into powder and mingled again. A part of this powder was pressed into two rectangular rods

As-pressed rods with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 838

As-pressed rods in an alumina box. Ready for sintering under air. The as-pressed rods are located on a lower punch which is made of alumina. The length of the long rod is 9 cm

As-pressed rods with fully oxidized composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$, i.e. all Nb and W ions are in their highest valence or oxidation state Nb^{5+} and W^{6+} , respectively

Sintered rods with composition $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5}$

Run No. 838

The as-pressed rods were 4 h sintered at 1225 °C under air. The sintering did result in a shrinkage of their length, namely $\Delta L \approx -4$ mm for the long rod and $\Delta L \approx -2$ mm for the short rod

Sample No. 826

A section from the 5 cm long as-grown crystalline material

As-grown crystalline material $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{69.5-y}$
Sample No. 826

5 cm long as-grown crystalline material

As-grown crystalline material $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{69.5-y}$

Sample No. 826

Crystalline pieces from section C8 of the as-grown material

As-grown crystalline material $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{69.5-y}$
Sample No. 826

Another picture from the same crystalline pieces
from section C8 of the as-grown material

As-grown crystalline material $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{69.5-y}$
Sample No. 826

Further picture from the same crystalline pieces
from section C8 of the as-grown material

As-grown crystalline material $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{69.5-y}$
Sample No. 826

Crystalline piece from section C6 of the as-grown material

826 C6 $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_x$ Thermogravimetry

Thermogravimetric oxidation in flowing synth. air up to the fully oxidized composition with $x = x_F = 69.5$ for the determination of the oxygen content $x = 69.5 - y$ by using a thermogravimetric analyzer NETZSCH TG 209 F1 Libra

Pulverized crystalline material from section C6 of the as-grown sample $\rightarrow x = 63.97$

826 C6 $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{63.97}$ Valences of the Nb and W ions

Valence or oxidation states of the
Nb and W ions in $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{63.97}$

The most likely scenario is $\text{W}^{4+} / 5d^2$

Charge neutrality and Sr^{2+} , Ca^{2+} , and $\text{O}^{2-} \rightarrow \text{Nb}^{4.52+} / 4d^{0.48}$

$2 (5d) + 19 \times 0.48 (4d) = 11.1$ d-electrons
per formula and assumed size of the unit cell

826 C6 $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ Powder x-ray diffraction

Powder x-ray diffraction pattern of pulverized crystalline material from section C6

Square root - linear plot • Background subtracted

All observed peaks fit to an orthorhombic $n = 5$ type structure

Available is an Excel file with the powder-x-ray diffraction data.
It is provided via the link which is specified on page 2

826 C6

Powder x-ray diffraction

	Observed peak position ($^{\circ}2\theta$)	d - spacing (\AA)	Relative intensity (%)	h k l from lattice parameter refinement
Lowest angle peak Its position indicates the structure type of $A_nB_nO_{3n+2}$, namely $n = 5$ in this case	5.41	16.31	5	0 0 2
Highest intensity peak	27.44	3.25	100	0 0 10

Available is an Excel file with the powder-x-ray diffraction data. It is provided via the link which is specified on page 2

826 C6 **Sr₁₇Ca₂Nb₁₉WO₆₄** **Powder x-ray diffraction**

Results of lattice parameter refinement with $(h\ k\ l)_{\max} = (10\ 10\ 20)$

Number of observed peaks	97
Number of indexed peaks	97
Number of unindexed peaks	0
Crystal structure type	$n = 5$ of $A_nB_nO_{3n+2}$
Crystal system	Orthorhombic
Bravais lattice	P
a (Å)	7.96
b (Å)	5.67
c (Å)	32.46
V (Å ³)	1465
$ 2\theta_{\text{obs}} - 2\theta_{\text{calc}} $ for all observed and calculated peaks	$\leq 0.071^\circ$
Figure of merit of the refinement or fit	16.8
Chi square of the refinement or fit	4.4×10^{-6}

Available is an Excel file with the powder-x-ray diffraction data.

826 C6

$\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$

Magnetic measurements

Crystalline piece C6-1 with $m = 221$ mg
from section C6 of the as-grown material

This piece was used to study its magnetic
properties by a SQUID magnetometer

826 C6 $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

11.1 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

826 C6 $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

11.1 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

The behavior of $\chi(T)$ in the range from 390 K to 70 K is similar to that of $A_nB_nO_{3n+2}$ type quasi-1D metals. Thus this $n = 5$ type material is potentially also a quasi-1D metal

826 C6 $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

11.1 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

Increase of $\chi(T)$ below 60 K due to paramagnetic impurities or defect states or 5d electrons which become localized ?

826 C6 $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ Magnetic susceptibility $\chi(T)$

DC magnetic moment $M(T)$ measured by a Quantum Design SQUID magnetometer MPMS3

11.1 d-electrons from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

D = diamagnetic contribution from closed electron shells of Sr^{2+} , Ca^{2+} , Nb^{5+} , W^{6+} , and O^{2-}

6 Conducting and metallic Carpy-Galy
phases $A_n B_n O_{3n+2} = ABO_x$

6.9.7 Magnetic susceptibility curves $\chi(T)$
of five compounds of the type
(Sr,Ca,Ba)₁₉Nb₁₉WO_x ($64 \leq x \leq 66$)
in one graphics ...

Magnetic susceptibility $\chi(T)$ of melt-grown Sr- and O-deficient $n = 5$ type $(\text{Sr,Ca,Ba})_{19}\text{Nb}_{19}\text{WO}_x$ ($64 \leq x \leq 66$)

$\chi(T)$ of the materials which are presented in the previous parts 6.9.2 - 6.9.6

The specified number of d-electrons per formula and assumed size of the unit cell are from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

Magnetic susceptibility $\chi(T)$ of melt-grown Sr- and O-deficient $n = 5$ type $(\text{Sr,Ca,Ba})_{19}\text{Nb}_{19}\text{WO}_x$ ($64 \leq x \leq 66$)

The Sr-deficient Schückel-Müller-Buschbaum type phases $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$ and $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$ differ from the other compounds

The specified number of d-electrons per formula and assumed size of the unit cell are from $\text{Nb}^{4+} / 4d^1$ and $\text{W}^{4+} / 5d^2$

6 Conducting and metallic Carpy-Galy
phases $A_n B_n O_{3n+2} = ABO_x$

6.9.8 The Sr-deficient Schückerl-Müller-
Buschbaum type phases

Comments and open questions ...

Let's first recall from part 6.7 the
crystal structure of the $n = 5$ type
Schückel-Müller-Buschbaum phase
 $\text{SrNbO}_{3.2} = \text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$
and the $n = 5$ type quasi-1D metal
 $\text{SrNbO}_{3.4} = \text{Sr}_5\text{Nb}_5\text{O}_{17} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{68} \dots$

The crystal structure of the $n = 5$ types $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ and $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$

Comments and open questions

- Do they have the same but Sr-deficient crystal structure as that of $\text{Sr}_5\text{Nb}_5\text{O}_{16} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ reported by K. Schückel and Hk. Müller-Buschbaum, i.e. do they have
 - a non-centrosymmetric space group ?
 - within a single layer or slab along the *c*-axis an asymmetric distribution of the Nb^{4+} and Nb^{5+} ions ?
 - within a single layer or slab along the *c*-axis an asymmetric distribution of the Nb – O polyhedra distortions ?
 - with reference to the stoichiometric $n = 5$ type $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$ fully ordered oxygen vacancies which are located at opposite boundaries of the layers or slabs ?
- Can the assumed doubled *a*-axis be confirmed by single crystal x-ray diffraction ?

The Sr-deficient Schückerl-Müller-Buschbaum type phases

Comments and open questions

- Do the W ions occupy only specific *B* or Nb sites within the unit cell or are they randomly distributed ?
- Can the assumed valence state of tungsten, namely $\text{W}^{4+} / 5d^2$, experimentally be verified ?
- Are these materials quasi-1D metals like the related stoichiometric $n = 5$ type quasi-1D metal $\text{Sr}_5\text{Nb}_5\text{O}_{17} = \text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$? If yes: Do the 5d electrons from the W ions contribute to the metallic behavior like the 4d electrons from Nb^{4+} ?
- The composition of the layered perovskite-related Sr- and O-deficient $n = 5$ type $(\text{Sr,Ca,Ba})_{19}\text{Nb}_{19}\text{WO}_{64} = (\text{Sr,Ca,Ba})_{0.95}\text{Nb}_{0.95}\text{W}_{0.05}\text{O}_{3.2} = A_{0.95}\text{BO}_{3.2}$ is close to that of the non-layered perovskite $A_{20}\text{B}_{20}\text{O}_{60} = \text{ABO}_3$. For comparison it should be mentioned that in the system LaTiO_x the homogeneity range of the non-layered perovskite structure extends from $x = 3$ to $x = 3.2$, see part 6.1

The Sr-deficient Schücker-Müller-Buschbaum type phases

Comments and open questions

- Are there related but insulating $n = 5$ type compounds $A_{19}B_{20}O_{64}$ or $A_{20}B_{20}O_{64}$ which are non-centrosymmetric, magnetoelectric, ferroelectric, and / or multiferroic ?
- Many of these comments and open questions can also be applied to the related melt-grown compounds which have a higher oxygen content, namely
 - $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{65.3}$ which is presented in part 6.9.4
 - $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{65.5}$ which is presented in part 6.9.3
 - $\text{Sr}_{19}\text{Nb}_{19}\text{WO}_{66}$ which is presented in part 6.9.2
- If the oxygen content of such type of materials is about 66.7 or smaller, then in principle an $n = 6$ type phase could arise but there are no indications for that. An example of an $n = 6$ type compound is the ferroelectric insulator $\text{Sr}_6\text{Nb}_4\text{Ti}_2\text{O}_{20} = \text{Sr}_{20}\text{Nb}_{13.33}\text{Ti}_{6.67}\text{O}_{66.67}$ ($\text{Nb}^{5+} / 4d^0$ and $\text{Ti}^{4+} / 3d^0$)

The Sr-deficient Schücker-Müller-Buschbaum type phases

Comments and open questions

- When considering a series of such type of materials with a higher oxygen content that approaches stepwise from higher values towards 64:
Is there a specific oxygen content x_c or a two-phase oxygen content range which separates the two single phases
 - centrosymmetric / non-centrosymmetric ?
 - symmetric / asymmetric distribution of the Nb^{4+} and Nb^{5+} ions ?
 - symmetric / asymmetric distribution of the Nb – O polyhedra distortions ?

6 Conducting and metallic Carpy-Galy phases $A_n B_n O_{3n+2} = ABO_x$

6.9.9 A nonlinear behavior of the magnetic moment $M(H)$ of the crossover region from a polycrystalline to a crystalline material suggests the existence of ferromagnetism in the system
Sr - Ca - Ba - Nb - W - O
or in one of its subsystem ...

As-grown crystalline $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5-y}$ and polycrystalline rods
Run / Sample No. 828 • See part 6.9.3

47 mm long as-grown crystalline material (1) plus polycrystalline seed rod (2) and remaining part of the polycrystalline feed rod (3)

Crossover region crystalline / polycrystalline of $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5-y}$ Sample No. 828 • Magnetic moment $M(H)$

DC magnetic moment $M(H)$ measured by a Quantum Design SQUID magnetometer MPMS3

Instead of an usual linear $M(H)$ behavior this particular curve is observed. It suggests the presence of a small amount of a ferromagnetic phase whose magnetic moment saturates with increasing field so that with further increasing field the linear contribution from a diamagnetic material appears.

Is it possible that the specimen was accidentally contaminated with a small amount of a ferromagnetic material during its preparation for the magnetic measurements? This cannot be completely ruled out. However, this appears unlikely because all specimens which were used for magnetic measurements were broken off from the crystalline material and / or seed rod and then mechanically fixed within a straw without using any metallic or magnetic tools / things / materials ...

Crossover region crystalline / polycrystalline of $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{69.5-y}$ Sample No. 828 • Magnetic moment $M(H)$

DC magnetic moment $M(H)$ measured by a Quantum Design SQUID magnetometer MPMS3

Therefore this particular $M(H)$ curve suggests the existence of a ferromagnetic compound or ferromagnetic interface phenomenon in the system Sr - Ca - Ba - Nb - W - O or in one of its subsystem

Also other samples were investigated. Some of them display a similar $M(H)$ behavior but most of them show an usual linear $M(H)$ curve. Examples are presented on the following pages ...

Table 64. Magnetic properties of some rare earth ions after Ref. [89,104]. Recall that $L = S, P, D, F, G, H, I$ stands for $L = 0, 1, 2, 3, 4, 5, 6$, respectively. g is the free-ion Lande factor after Eq. (19). q_{th} is the theoretical free-ion value of the effective magnetic moment in units of the Bohr magneton μ_B after Eq. (18). Δ is the energy difference between the first excited state $^{2S+1}L_{J+1}$ and the ground state $^{2S+1}L_J$ of the multiplet. χ_V is the molar Van Vleck paramagnetic susceptibility after Eq. (14). The parameter $\xi = 2S(L+1)/[g^2J(J+1)^2\Delta]$, when multiplied with the temperature T , represents the ratio of the temperature-independent Van Vleck susceptibility χ_V to the Curie susceptibility $\chi_C = C/T$. ¹Here $\xi = \infty$ indicates symbolically the exclusive presence of the Van Vleck paramagnetism because the Curie susceptibility is absent owing to $J = 0$. ²Due to $L = 0$ there is no spin-orbit interaction and therefore Δ does not exist because the different levels of a multiplet arise from the spin-orbit coupling.

Magnetic susceptibility of (free) samarium and europium ions

$\text{Sm}^{3+} (4f^5)$ → Langevin paramagnetism (Curie or Curie-Weiss behavior)
plus significant contribution of Van Vleck paramagnetism

Sm^{2+} and Eu^{3+} (both $4f^6$) → Only Van Vleck (total angular momentum $J = 0$)

$\text{Eu}^{2+} (4f^7)$ → Only Langevin (orbital angular momentum $L = 0$)

Langevin paramagnetism results from states with different m_J

Van Vleck paramagnetism results from states J and $J + 1$

Magnetic susceptibility $\chi(T)$ of conducting $n = 5$ Carpy-Galy phases $Ln_nTi_nO_{3n+2} = LnTiO_x$ and the cubic pyrochlore $EuTiO_{3.5}$

The conducting materials (quasi-1D metals ?) comprise a mixed valence Ti^{4+} ($3d^0$) / Ti^{3+} ($3d^1$) and χ is dominated by the Ln^{3+} ions

$EuTiO_{3.5}$ is a Ti^{4+} ($3d^0$) insulator

Fig. 56. Log-linear plot of the molar magnetic susceptibility $\chi(T)$ in fields of $H \leq 500$ G of some titanates $LnTiO_x$: The $n = 5$ electrical conductors $CeTiO_{3.40}$ ($3d^{0.20}$), $PrTiO_{3.41}$ ($3d^{0.18}$), $NdTiO_{3.42}$ ($3d^{0.16}$), $SmTiO_{3.37}$ ($3d^{0.26}$), and the insulator $EuTiO_{3.50}$ ($3d^0$) with pyrochlore structure. The susceptibility results predominantly from the paramagnetic moments of the rare earth ions Ln^{3+} . Therefore this plot represents a comparison of the magnitude and the temperature dependence of $\chi(T)$ resulting from Ce^{3+} , Pr^{3+} , Nd^{3+} , Sm^{3+} and Eu^{3+} . J is the quantum number of the total angular momentum of Ln^{3+} and q_{th} the associated theoretical free-ion value of the effective magnetic moment, see Table 64. The susceptibility of the Ce^{3+} , Pr^{3+} and Nd^{3+} titanates displays a Curie-Weiss behavior, see Fig. 52, 59 and Table 65, 67 and 69. The susceptibility of $SmTiO_{3.37}$ is markedly influenced by the Van Vleck type paramagnetism, see Table 64 and also Fig. 51 and 52. The paramagnetic susceptibility of $EuTiO_{3.50}$ results exclusively from the Van Vleck type paramagnetism, see Table 64 and also Fig. 54.

Abstract: The stability limit between the layered-perovskite and pyrochlore structures was investigated for $\text{Ln}_2\text{Ti}_2\text{O}_7$ (Ln = lanthanide) thin films grown on (110)-oriented SrTiO_3 substrate by the sol-gel route. In bulk, for standard conditions of pressure and temperature, these oxides adopt the layered-perovskite structure for Ln = La to Nd while they crystallize in the pyrochlore one for Sm to Lu. When grown in thin films on (110)-oriented SrTiO_3 substrates, the frontier separating these two structures is shifted. High-resolution X-ray diffraction measurements evidence the **stabilization of a metastable (00l) oriented layered-perovskite structure for $\text{Sm}_2\text{Ti}_2\text{O}_7$, $\text{Eu}_2\text{Ti}_2\text{O}_7$, and $\text{Gd}_2\text{Ti}_2\text{O}_7$** . Such stabilization is explained by a combination of both the strains induced by the substrate in the film and the good lattice match between the substrate and the metastable layered-perovskite oxide. The stabilization of layered-perovskite structures in thin films opens interesting perspectives in terms of development of new ferroelectric/piezoelectric devices, keeping in mind that the isostructural $\text{La}_2\text{Ti}_2\text{O}_7$ and $\text{Nd}_2\text{Ti}_2\text{O}_7$ possess a very high Curie temperature ($T_c \approx 1500$ °C). Finally, the role played by the lanthanide precursor (nitrate or chloride) in the stabilization of the layered-perovskite structure is highlighted and prediction for stabilization of other new layered-perovskite compounds in the $\text{Ln}_2\text{B}_2\text{O}_7$ (B = Zr, Mn) system for thin films deposited on the (110)-oriented SrTiO_3 substrate is reported.

Abstract

The synthesis by the sol-gel route of metastable $\text{Sm}_2\text{Ti}_2\text{O}_7$ thin film is reported. While for standard conditions of pressure and temperature, the $\text{Sm}_2\text{Ti}_2\text{O}_7$ compound crystallizes in a cubic pyrochlore structure, in the form of a thin film (grown on (110)-oriented SrTiO_3 substrate), a monoclinic layered perovskite structure is stabilized by strain effects induced by the substrate. Under these conditions, (00l)-oriented $\text{Sm}_2\text{Ti}_2\text{O}_7$ oxide is isostructural to ferroelectric $\text{Ln}_2\text{Ti}_2\text{O}_7$ (with Ln = La, Ce, Pr and Nd) phases, which is already well known. Studies by Selected Area Electron Diffraction (SAED) reveal the existence of a systematically twinned structure and the presence of a fault in the stacking of the perovskite layers. Piezoresponse Force Microscopy (PFM) measurements confirm undoubtedly the ferroelectricity in this metastable phase.

The system $\text{Pr}_{1-y}\text{Ca}_y\text{Ti}_{1-y}\text{Nb}_y\text{O}_{3.50}$ (Pr^{3+} , Ti^{4+} , and Nb^{5+})

Powder x-ray diffraction pattern of melt-grown $\text{Pr}_{1-y}\text{Ca}_y\text{Ti}_{1-y}\text{Nb}_y\text{O}_{3.50}$

$\text{PrTiO}_{3.50}$ and $\text{CaNbO}_{3.50}$ are $n = 4$ type ferroelectric insulators

Nevertheless, some intermediate compositions crystallize in the cubic pyrochlore structure, e.g. that with $y = 0.4$

8 Carpy-Galy phases

$A_n B_n O_{3n+2} = ABO_x$ allow a special kind of micro or nano patterning by an electron beam

8.3 A potential novel magnetoelectric or multiferroic system: Weak ferromagnetic LaTiO_3 micropillars in a ferroelectric matrix $\text{LaTiO}_{3.5}$...

A potential novel magnetoelectric or multiferroic system: Weak ferromagnetic LaTiO_3 micropillars in ferroelectric $\text{LaTiO}_{3.5}$

The $n = \infty$ perovskite type LaTiO_3 is known as a weak ferromagnet / canted antiferromagnet with $T_N \approx 150$ K. The $n = 4$ type $\text{LaTiO}_{3.5}$ is known as a high- T_c ferroelectric with $T_c = 1770$ K.

If it is possible to create weak ferromagnetic LaTiO_3 micropillars in a ferroelectric $\text{LaTiO}_{3.5}$ matrix, then this raises the question if the electric and magnetic properties / quantities are coupled. If yes, then this represents a novel magnetoelectric system and potentially also a novel multiferroic system.

Sketch of a hypothetical system:

Weak ferromagnetic LaTiO_3 micropillars
in a ferroelectric $\text{LaTiO}_{3.5}$ matrix

8 Carpy-Galy phases

$A_n B_n O_{3n+2} = ABO_x$ allow a special kind of micro or nano patterning by an electron beam

8.4 Another suggested system:

$NaWO_x$ ($3 \leq x < 3.5$) micropillars in a $NaWO_{3.5}$ matrix ...

NaWO_x ($3 \leq x < 3.5$) micropillars in a $\text{NaWO}_{3.5}$ matrix ?

As shown on the page after next the insulating $\text{NaWO}_{3.5} = \text{Na}_2\text{W}_2\text{O}_7$ ($\text{W}^{6+} / 5d^0$) displays two structural modifications which are both orthorhombic. When synthesized under high pressure it adopts the $n = 4$ type structure which is potentially ferroelectric. Maybe it is also possible to stabilize the $n = 4$ type structure in a $\text{NaWO}_{3.5}$ thin film by strain by an appropriate substrate.

Stoichiometric $n = \infty$ pervoskite type NaWO_3 ($\text{W}^{5+} / 5d^1$) was synthesized under high pressure and displays a metallic resistivity behavior.

Yuya Ikeuchi et al., Inorganic Chemistry 58 (2019) 6790

Perhaps NaWO_3 micropillars or NaWO_x ($3 < x < 3.5$) micropillars can be created in a $\text{NaWO}_{3.5}$ matrix.

Sketch of a hypothetical system:

NaWO_3 or NaWO_x ($3 < x < 3.5$) micropillars
in a $\text{NaWO}_{3.5}$ matrix

Among others, such a system appears interesting with respect to the reported evidence for high- T_c superconductivity in the system Na – W – O which is presented in the following part 9 ...

- Strong experimental evidence for high- T_c superconductivity without Cu
- In spite of many efforts the superconducting phase could not be identified

Speculation: High- T_c superconducting phase Na_xWO_y could be of the type $A_nB_nO_{3n+2}$

Progress in Solid State Chemistry **36** (2008) 253

NaWO_x ($3.5 \geq x \geq 3$) and $A_nB_nO_{3n+2} = ABO_x$

No indications for superconductivity in a polycrystalline sintered $n = 5$ type composition $\text{NaWO}_{3.4}$

Synthesis approach:

$\text{WO}_{1.98}$ = Tungsten dioxide with thermogravimetrically determined oxygen content 1.98

Pre-reacted for 6 h at 600 °C under air. After mingling the pre-reacted material with $\text{WO}_{1.98}$ the obtained powder was pressed into a rectangular shape and heated and sintered for 6 h at 700 °C under argon in the GERO tube furnace.

A polycrystalline sintered $n = 5$ type composition $\text{NaWO}_{3.4}$

Sample No. 704 • Prepared at the ETH Zurich in 2012

Material is probably multiphase

Powder x-ray diffraction was not performed

The magnetic moment $M(T)$ and susceptibility $\chi(T)$ of a piece from this material was measured by a SQUID magnetometer in the temperature range $2 \text{ K} \leq T \leq 330 \text{ K}$.

$\chi(T)$ is weakly diamagnetic and nearly temperature-independent and no indication for superconductivity was detected.

Acknowledgement: F. L. thanks Bertram Batlogg (ETH Zurich) who performed the magnetic measurement with his Quantum Design SQUID Magnetometer MPMS XL

No indications for superconductivity in a polycrystalline sintered $n = 6$ type composition $\text{NaWO}_{3.33}$

Synthesis approach analogous to what is described on the previous page but with another appropriate ratio $\text{WO}_3 / \text{WO}_{1.98}$

Two as-pressed rods with composition $\text{NaWO}_{3.33}$

Rods with composition $\text{NaWO}_{3.33}$ after they were heated and sintered under argon

Run / Sample No. 711 • Prepared at the ETH Zurich in 2013

Material is probably multiphase • Powder x-ray diffraction was not performed

Processing the sintered rods by floating zone melting did not work because of a difficult melting behavior and strong bending of the seed rod in the mirror furnace

The magnetic moment $M(T)$ of a piece from the sintered rods was measured by a SQUID magnetometer in the temperature range $2 \text{ K} \leq T \leq 300 \text{ K}$ and no indication for superconductivity was detected. **Acknowledgement:** F. L. thanks Marisa Medarde (PSI) and Mickael Morin (PSI) for performing a magnetic measurement with a Quantum Design SQUID magnetometer MPMS XL and Nicholas Bingham (PSI) for performing a magnetic measurement with a Quantum Design SQUID magnetometer MPMS3

Structure type $j = 1$
of $A_{j+1}B_jO_{3j+1}$

Grown under synth. air

Samples prepared at the
IBM Zurich Research Laboratory

Photos taken at the ETH Zurich

The original intention was to try to synthesize the $j = 2$ type $\text{Sr}_3\text{Ru}_2\text{O}_7$ via the melt. However, $\text{Sr}_3\text{Ru}_2\text{O}_7$ did never appear and always Sr_2RuO_4 did arise, nearly independent of the ratio Sr / Ru. The experiments were difficult because of a strong evaporation of RuO_x . Nevertheless, nice crystalline pieces of Sr_2RuO_4 could be obtained from the inner part of the melt-grown material. Resistivity measurements on Sr_2RuO_4 crystals revealed a metallic behavior along the layers. In crystalline form Sr_2RuO_4 was the first metallic substrate for the epitaxial growth of thin films of high- T_c superconductors like $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$

Later it was discovered that the Sr_2RuO_4 crystals itself are superconducting at low temperatures with $T_c \approx 1$ K. Despite of its low T_c the Sr_2RuO_4 gained considerable attention because of its unconventional superconducting properties. Sr_2RuO_4 is isostructural to $(\text{La},\text{Ba})_2\text{CuO}_4$ in which J. G. Bednorz and K. A. Müller discovered in 1986 superconductivity up to 30 K. For updates and references until May 2019 see the program of the **conference “Strontium Ruthenate - 25 years of a puzzling superconductor”** which took place in May 2019 at the ETH Zurich:

Structure type $m = 5$

Blue-black electrical conductor

Observation at melt-grown layered oxides:

Usually the layers grow parallel or 45 degrees declined to the axial direction of the as-grown material. Concerning own experiments this compound is one of very few examples where the layers did grow perpendicular to the axial direction of the as-grown material
