Abstract:	It is generally assumed that restoring biodiversity will enhance diversity and ecosystem functioning. However, to date, it has rarely been evaluated whether and how restoration efforts manage to rebuild biodiversity and multiple ecosystem functions (ecosystem multifunctionality) simultaneously. Here, we quantified how three

restoration methods of increasing intervention intensity (harvest only < topsoil removal < topsoil removal + propagule addition) affected grassland ecosystem multifunctionality 22 years after the restoration event. We compared restored with intensively managed and targeted semi-natural grasslands based on 13 biotic and abiotic, above- and belowground properties. We found that all three restoration methods improved ecosystem multifunctionality compared to intensively managed grasslands and developed towards the targeted semi-natural grasslands. However, whereas higher levels of intervention intensity reached ecosystem multifunctionality of targeted semi-natural grasslands after 22 years, lower intervention missed this target. Moreover, we found that topsoil removal with and without seed addition accelerated the recovery of biotic and aboveground properties, and we found no negative long-term effects on abiotic or belowground properties despite removing the top layer of the soil. We also evaluated which ecosystem properties were the best indicators for restoration success in terms of accuracy and cost efficiency. Overall, we demonstrated that low-cost measures explained relatively more variation of ecosystem multifunctionality compared to high-cost measures. Plant species richness was the most accurate individual property in describing ecosystem multifunctionality, as it accounted for 53% of ecosystem multifunctionality at only 4% of the costs of our comprehensive multifunctionality approach. Plant species richness is the property that typically is used in restoration monitoring by conservation agencies. Vegetation structure, soil carbon storage and water holding capacity together explained 70% of ecosystem multifunctionality at only twice the costs (8%) of plant species richness, which is, in our opinion, worth considering in future restoration monitoring projects. Hence, our findings provide a guideline for land managers how they could obtain an accurate estimate of aboveground-belowground ecosystem multifunctionality and restoration success in a highly cost-efficient way.

20 ABSTRACT

21 It is generally assumed that restoring biodiversity will enhance diversity and ecosystem functioning.
22 However, to date, it has rarely been evaluated whether and how restoration efforts manage to rebuild
23 biodiversity and multiple ecosystem functions (ecosystem multifunctionality) simultaneously. Here, we
24 quantified how three restoration methods of increasing intervention intensity (harvest only < topsoil
25 removal < topsoil removal + propagule addition) affected grassland ecosystem multifunctionality 22 years
26 after the restoration event. We compared restored with intensively managed and targeted semi-natural
27 grasslands based on 13 biotic and abiotic, above- and belowground properties. We found that all three
28 restoration methods improved ecosystem multifunctionality compared to intensively managed grasslands
29 and developed towards the targeted semi-natural grasslands. However, whereas higher levels of
30 intervention intensity reached ecosystem multifunctionality of targeted semi-natural grasslands after 22
31 years, lower intervention missed this target. Moreover, we found that topsoil removal with and without
32 seed addition accelerated the recovery of biotic and aboveground properties, and we found no negative
33 long-term effects on abiotic or belowground properties despite removing the top layer of the soil. We also
34 evaluated which ecosystem properties were the best indicators for restoration success in terms of accuracy
35 and cost efficiency. Overall, we demonstrated that low-cost measures explained relatively more variation
36 of ecosystem multifunctionality compared to high-cost measures. Plant species richness was the most
37 accurate individual property in describing ecosystem multifunctionality, as it accounted for 53% of
38 ecosystem multifunctionality at only 4% of the costs of our comprehensive multifunctionality approach.
39 Plant species richness is the property that typically is used in restoration monitoring by conservation
40 agencies. Vegetation structure, soil carbon storage and water holding capacity together explained 70% of
41 ecosystem multifunctionality at only twice the costs (8%) of plant species richness, which is, in our
42 opinion, worth considering in future restoration monitoring projects. Hence, our findings provide a
43 guideline for land managers how they could obtain an accurate estimate of aboveground-belowground
44 ecosystem multifunctionality and restoration success in a highly cost-efficient way.

48 INTRODUCTION

49 Semi-natural grasslands are an integral part of the Western and Central European cultural landscape
50 and result from traditional farming over centuries (Van Dijk 1991, Poschlod and Wallis De Vries 2002,
51 Bobbink et al. 2011). These grasslands are among the most species-rich ecosystems and represent
52 biodiversity hotspots that harbor specialized plant and animal communities with high numbers of rare and
53 endangered species (Dengler et al. 2014). Semi-natural grasslands are characterized by low productivity
54 and high structural heterogeneity with a diverse mosaic of ecological niches and microhabitats (Diacon-
55 Bolli et al. 2012). They are found on oligo- to mesotrophic soils that are sensitive to eutrophication
56 (Bobbink et al. 1998, Bobbink et al. 2011). Maintaining these grasslands requires low-input agricultural
57 management to prevent accumulation of soil nutrients and to impede reforestation (Poschlod and Wallis
58 De Vries 2002). Semi-natural grasslands also provide numerous ecosystem functions and services. For
59 example, by supporting high abundance and diversity of invertebrates, they may provide pollination and
60 pest control services for surrounding agricultural areas (Byrne and delBarco-Trillo 2019). They can be
61 important for soil and water protection against pollution (Peciña et al. 2019) and may act as hydrological
62 buffers (Gimmi et al. 2011). Semi-natural grasslands were also found to mitigate droughts or floods and
63 reduce carbon dioxide emissions due to their enhanced carbon storage capacities compared to arable land
64 (Peciña et al. 2019). However, semi-natural grasslands are under multiple pressures.

65 Since the late 19th century, semi-natural grasslands have been drastically reduced in their extent and
66 connectivity (Wallis De Vries et al. 2002) as their low productivity made them prime for conversion into
67 more profitable high-input agricultural land, or on the contrary, for complete abandonment (Quétier et al.
68 2007, Török and Dengler 2018). In Switzerland, for example, 95% of semi-natural grasslands were lost
69 during the course of the past century (Lachat et al. 2010). As a consequence, efforts to protect the
70 remaining areas were greatly enhanced, but their ongoing loss could not be stopped (Gattlen et al. 2017).
71 Today, these grasslands represent species-rich islands in a landscape dominated by intensive agriculture.
72 It became evident that sustainable conservation has to integrate restoration to actively extend and re-

73 connect these fragmented remnants and to re-enable metapopulation dynamics and genetic exchange of
74 biotic communities among the isolated patches (Lachat et al. 2010). Hence, converting adjacent
75 intensively managed grasslands into semi-natural grasslands became the focus of restoration projects
76 (Kiehl et al. 2010, Kardol and Wardle 2010). Intensively managed grassland generally represents a highly
77 eutrophic and homogenized habitat, dominated by only a few competitive generalist species while habitat
78 specialists are scarce (De Deyn et al. 2003, Kardol and Wardle 2010). Thus, successful conversion of
79 such intensively managed grasslands into nutrient poor and species rich communities relies on
80 overcoming their agricultural legacy, which is preserved in overabundant soil nutrients as well as poor
81 species and propagule availability (Bakker and Berendse 1999, McLauchlan 2006, Brinkman et al. 2017).

82 Various restoration strategies have been tested over the past decades. They affect above- and
83 belowground, biotic and abiotic properties differently depending on their intervention intensity (e.g.,
84 Marrs et al. 1998, Kiehl and Pfadenhauer 2007, Kardol et al. 2008, Frouz et al. 2009, Suding 2011). Mild
85 interventions, such as cessation of fertilization and multiple plant biomass harvests, have been rarely
86 successful in lowering the high availability of soil nutrients and re-establishing targeted plant
87 communities. Conversely, more severe interventions, such as topsoil removal with and without seed
88 addition, were found to be highly successful in restoring oligotrophic grassland ecosystems (see review in
89 Kiehl et al. 2010). However, removal of the nutrient-rich topsoil, typically a layer of 20 to 50 cm,
90 substantially affects belowground biota and abiotic soil conditions, and is therefore viewed rather
91 critically (see Geissen et al. 2013).

92 Yet, to evaluate restoration success, usually only a few aboveground biotic properties, typically plant
93 community composition, sometimes the presence/absence of selected insect species or taxa (e.g.,
94 grasshoppers, beetles) are used (e.g., Patzelt et al. 2001, Kardol et al. 2005, Kiehl & Wagner 2006, Kiehl
95 & Pfadenhauer 2007, Klimkowska et al. 2007, Verhagen et al. 2008, Neff et al. 2020). More exhaustive
96 evaluations are lacking and only few studies assessed belowground community composition and soil
97 properties to determine restoration success (e.g., Kardol et al. 2009b, Frouz et al. 2009, Wubs et al. 2016,
98 Resch et al. 2019). As restoration methods should enhance and re-establish biodiversity and ecosystem

99 functioning both above- and belowground, success should be evaluated based on a comprehensive
100 assessment of biotic and abiotic, above- and belowground properties, such as taxonomic and structural
101 diversity, and soil functions and processes (Havlicek 2012, Greiner et al. 2018, Gann et al. 2019). Thus, a
102 multifunctional approach could be highly suitable to validate successful re-establishment of the targeted
103 species or ecosystem properties and functions over time (see review in Manning et al. 2018, but also see
104 Meyer et al. 2015, Costantini et al. 2016).

105 In the present study, we assessed how three restoration methods of different intervention intensities,
106 i.e., *Harvest only* (biomass removal), *Topsoil* (topsoil removal), and *Topsoil+Propagules* (topsoil
107 removal plus addition of target plant species), succeeded in restoring ecosystem multifunctionality. We
108 included 13 properties, namely aboveground arthropod richness, belowground faunal and microbial taxon
109 richness, plant species richness, vegetation structure, above- and belowground functional diversity and
110 food-web complexity, soil heterogeneity, soil carbon (C) storage, water holding capacity, nutrient
111 retention capacity and soil net nitrogen (N) mineralization in our ecosystem multifunctionality metric.
112 Restoration success was compared to both intensively managed grasslands (*Initial state*) and ancient
113 semi-natural grasslands (*Target state*). The evaluation took place 22 years after restoration methods were
114 implemented. To our knowledge, this is the first long-term study that combined aboveground and
115 belowground ecosystem multifunctionality to evaluate the recovery of targeted ecosystem properties after
116 grassland restoration. As measuring and assessing various ecosystem properties is cost-intensive, we
117 conducted a “cost-benefit analysis” to determine which and how many ecosystem properties are needed to
118 define ecosystem multifunctionality in restored grasslands as accurately as possible, but at affordable
119 costs (effort, infrastructure, expert knowledge). This analysis should help environmental agencies that
120 supervise restoration programs in their decision-making process. Overall, we aimed to answer the
121 following research questions:

- 122 1. Does multifunctionality differ between intensively managed and semi-natural grasslands?
- 123 2. Are the different restoration methods successful in restoring grassland multifunctionality?

- 124 3. How much do biotic and abiotic, above- and belowground properties contribute to ecosystem
125 multifunctionality?
- 126 4. Which ecosystem properties are the best indicators to accurately describe multifunctionality in
127 restored grasslands in a cost-effective way?

128 MATERIAL AND METHODS**129 Study area**

130 The study was conducted in the Canton of Zurich, Switzerland, in and around two nature reserves
131 *Eigental* and *Altläufe der Glatt* ($47^{\circ}27'$ to $47^{\circ}29'$ N, $8^{\circ}37'$ to $8^{\circ}32'$ E, 417 to 572 m a.s.l.). All studied
132 grasslands were located with a radius of approximately 4 km. Average monthly temperatures range from
133 0.7 ± 2.0 °C (January) to 19.0 ± 1.5 °C (July), and monthly precipitation range from 60 ± 42 mm
134 (January) to 118 ± 46 mm (July [maxima]; 1989-2017; MeteoSchweiz 2018). The two nature reserves
135 contain small-scale grassland mosaics differing in their nutrient and water availability. In our study, we
136 focused on semi-dry and semi-wet oligo- to mesotrophic grasslands characterized by high plant species
137 richness and groundwater fluctuations throughout the year (Delarze et al. 2015, see also Resch et al.
138 2019).

139

140 Experimental design and sampling

141 A large-scale restoration experiment to expand and reconnect isolated remnants of species-rich
142 grasslands was initiated in the nature reserve *Eigental* in 1990. Twenty hectares of adjacent intensive
143 grasslands were chosen for restoration. In 1995, three restoration methods of increasing intervention
144 intensities were implemented. The goal of all three methods was to lower the availability of soil nutrients
145 and hence, facilitate ecosystem development towards the targeted nutrient-poor grasslands. These
146 methods were: *Harvest only* (hay harvest twice a year), *Topsoil* (removal of the nutrient-rich topsoil), and
147 *Topsoil+Propagules* (topsoil removal combined with the application of hay from target vegetation;
148 further details see Resch et al. 2019). Plant biomass harvest (once a year in late summer/early autumn)
149 commenced in *Topsoil* and *Topsoil+Propagules* five years after the soils were removed and is still
150 ongoing today (see Appendix 1: Table S1). We measured restoration success by comparing the three
151 restoration methods with intensively managed (*Initial*) and semi-natural grasslands (*Target*) 22 years after
152 restoration. *Initial* grassland sites share the same agricultural history as the restored sites: mowing and

153 subsequent fertilizing (manure) up to five times a year, as well as different tillage regimes (see Appendix
154 S1: Table S1; Resch et al. 2019). *Target* sites were the sites from which hay for seeding the
155 *Topsoil+Propagules* sites was collected. Soil conditions (i.e., soil types, soil texture) were comparable to
156 those found in the restored grasslands (see Appendix S1: Table S1; Resch et al. 2019). Additionally,
157 *Target* sites were selected to represent a variety of semi-natural grasslands, including semi-dry to semi-
158 wet conditions. In *Target* grasslands, biomass is harvested once a year in late summer or early autumn.
159 Eleven 5 m x 5 m (25 m²) plots were randomly established in each of the five treatments (in total 55 plots;
160 for a detailed map see Neff et al. 2020). An additional 2 m x 2 m (4 m²) subplot was randomly established
161 at least 2 m away from each 25 m² plot for destructive sampling (see details below). Data sampling took
162 place between June and September 2017.

163

164 *Vegetation properties*

165 All plant species were identified within the 25 m² plots (nomenclature: Lauber and Wagner 1996) in
166 mid-June 2017 (in total 250 species). Vegetation structure and plant biomass were assessed diagonally on
167 a transect of 2 m x 10 cm within the 25 m² plot in early July 2017. We measured the maximum and mean
168 height of the vegetation at the start, middle and end of the transect and calculated the standard deviation
169 of these measures to describe vegetation structural heterogeneity (Schuldt et al. 2019). Thereafter,
170 biomass was clipped on the entire transect to 1 cm height, sorted into five functional groups (graminoids,
171 forbs, legumes, litter, and woody species; Data repository: <https://doi.org/10.16904/envidat.169>), dried at
172 60 °C for 48 h, and weighed (Meyer et al. 2015).

173

174 *Aboveground arthropods*

175 Aboveground arthropods were sampled at two locations in each 25 m² plot in early July 2017 (see also
176 Neff et al. 2020). Briefly, two cylindrical baskets (50 cm diameter, 67 cm height; woven fabric) were
177 thrown simultaneously from outside the plot into two opposite corners. A closable mosquito mesh sleeve
178 was mounted to the top of the baskets and an integrated metal ring at the bottom was fixed to the ground

179 with metal stakes to assure that insects could not escape. A suction sampler (Vortis, Burkhard
180 Manufacturing Co. Ltd., Hertfordshire, England) was then inserted into one of the baskets through the
181 opening of the sleeve and the plot was "vacuumed" twice for 105 seconds with a 30 seconds break. The
182 collected animals were immediately transferred into 70% ethanol. Arthropods were sorted and assigned to
183 23 taxonomic groups (Appendix S1: Table S3; Data repository: <https://doi.org/10.16904/envidat.169>).
184 Holometabolic larvae were lumped into one category while hemimetabolic larvae were grouped
185 separately from adults in the respective taxonomic rank. We used mean values of individuals per plot for
186 total abundance. Aboveground arthropod richness was defined by the number of different taxa to lowest
187 taxonomic level (in total 23 taxa). All taxa were assigned to one of five trophic levels: 1) primary
188 producers, 2) primary consumers, 3) secondary consumers, 4) tertiary consumers, and 5) quaternary
189 consumers (Appendix S1: Table S3).

190

191 *Belowground fauna*

192 Sampling of all belowground fauna took place in mid-July 2017. Earthworms were sampled in two 30
193 cm x 30 cm x 20 cm soil monoliths at two opposite corners of the 25 m² plot (opposite to aboveground
194 arthropod sampling). The excavated soil monolith was broken by hand, all earthworms collected and
195 immediately transferred in a 4% formaldehyde solution. Thereafter, earthworm individuals were
196 identified to species level (in total 10 taxa; Christian and Zicsi 1999) and species assigned to three
197 functional groups (Appendix 1: Table S3; Data repository: <https://doi.org/10.16904/envidat.169>; Bouché
198 1977).

199 To assess soil arthropod communities, we randomly collected one undisturbed soil core (5 cm
200 diameter, 12 cm depth) in each 4 m² subplot with a slide hammer corer lined with a plastic sleeve (AMS
201 Samplers, American Falls, Idaho, USA). Soil arthropods were extracted using Berlese-Tullgren funnels (3
202 mm mesh), starting the day of sampling and lasting 14 days. Individuals were stored in 70% ethanol. Soil
203 arthropods were assigned to 41 taxonomic groups and 4 feeding types (Appendix 1: Table S3; Data
204 repository: <https://doi.org/10.16904/envidat.169>). Holometabolic and hemimetabolic larvae were treated

205 as previously described for aboveground arthropods. Belowground arthropod richness refers to the 41
206 taxonomic groups.

207 For soil nematode sampling, we randomly collected eight soil cores of 2.2 cm diameter (Giddings
208 Machine Company, Windsor, CO, USA) within each 4 m² subplot to a depth of 12 cm. The eight cores
209 were combined, gently homogenized, placed in coolers, kept at 4 °C and transported to the laboratory at
210 NIOO in Wageningen (NL) within one week after collection. Free-living nematodes were extracted from
211 200 g of fresh soil using Oostenbrink elutriator (Oostenbrink 1960) and prepared for morphological
212 identification and quantification as described by Resch et al. (2019). Nematodes were identified to family
213 level (39 taxa) according to Bongers (1988), assigned to 17 functional groups, 5 feeding types and 5
214 colonizer-persister (C-P) classes (Appendix 1: Table S3; Data repository:
215 <https://doi.org/10.16904/envidat.169>; Yeates et al. 1993, Bongers 1990, Resch et al. 2019).

216 We randomly collected two more soil cores (2.2 cm diameter x 12 cm depth) within each 4 m² subplot
217 to determine soil microbial communities. Again, the soil cores were combined, homogenized, placed in
218 coolers and transported to the laboratory at WSL in Birmensdorf (Switzerland) where the metagenomic
219 DNA was extracted from 8 g sieved soil (2 mm) using the DNeasy PowerMax Soil Kit (Qiagen, Hilden,
220 NRW, GER) according to the manufacturer's instructions. PCR amplification of the V3-V4 region of the
221 prokaryotic small-subunit (16S) and the ribosomal internal transcribed spacer region (ITS2) of eukaryotes
222 was performed with 1 ng of template DNA utilizing PCR primers and conditions as previously described
223 (Frey et al., 2016). PCRs were run in triplicates and pooled. The pooled amplicons were sent to the
224 Genome Quebec Innovation Centre (Montreal, QC, Canada) for barcoding using the Fluidigm Access
225 Array technology (Fluidigm) and paired-end sequencing on the Illumina MiSeq v3 platform (Illumina
226 Inc., San Diego, CA, USA). Quality filtering, clustering into operational taxonomic units (OTUs) and
227 taxonomic assignment were performed as described by Frey et al. (2016) and Adamczyk et al. (2019). We
228 used a customised pipeline largely based on UPARSE (Edgar 2013) implemented in USEARCH v. 9.2
229 (Edgar 2010). After discarding singletons of dereplicated sequences, clustering into OTUs with 97%
230 sequence similarity was performed (Edgar 2013). Quality-filtered reads were mapped on the filtered set of

231 centroid sequences. Taxonomic classification of prokaryotic and fungal sequences was conducted
232 querying against most recent versions of SILVA (v.132, Quast et al. 2013) and UNITE (v.8, Nilsson et al.
233 2018). Only taxonomic assignments with confidence rankings equal or higher than 0.8 were accepted
234 (assignments below 0.8 set to unclassified). Prokaryotic OTUs assigned to mitochondria or chloroplasts
235 as well as eukaryotic OTUs assigned other than fungi were removed prior to data analysis. In addition,
236 prokaryotic and fungal datasets were filtered to discard singletons and doubletons. Thereafter, OTU
237 abundance matrices were rarefied to the lowest number of sequences per community, to normalize the
238 total number of reads and achieve parity between samples (Prokaryota: 29,843 reads; Fungi: 26,690
239 reads). Finally, prokaryotic and fungal observed richness (number of OTUs) were estimated (Prokaryota:
240 14,010 OTUs; Fungi: 5,813 OTUs). For prokaryotes, we distinguished five and for fungi six functional
241 types based on lowest taxonomic resolution (Appendix 1: Table S3; Data repository:
242 <https://doi.org/10.16904/envidat.169>; Nguyen et al. 2016, Tedersoo et al. 2014). Belowground taxon
243 richness was defined by the total number of earthworm, arthropod, nematode, fungi, and prokaryote taxa
244 assigned to lowest taxonomic level. Finally, all belowground taxa were assigned to the same five trophic
245 levels as the aboveground arthropods (Appendix 1: Table S3; Data repository:
246 <https://doi.org/10.16904/envidat.169>).
247

248 *Soil chemical and physical properties, soil nitrogen mineralization*
249 We randomly collected three 5 cm diameter x 12 cm depth soil samples in each 4 m² subplot with a
250 slide hammer corer (AMS Samplers, American Falls, Idaho, USA), pooled them and then made two
251 subsamples. One was field-fresh and stored at 3 °C until analysis, the other was dried for 48 h at 60 °C
252 and passed through a 4 mm mesh. From the dried sample, we measured soil pH potentiometrically in 0.01
253 M CaCl₂ (soil:solution ratio=1:2, 30 minutes equilibration time). Total and organic carbon content were
254 measured on fine-ground samples (≤ 0.5 mm) by dry combustion using a CN analyzer NC 2500 (CE
255 Instruments, Wigan, United Kingdom). Inorganic carbon of samples with a pH > 6.5 was removed with
256 acid vapor prior to analysis of organic carbon (Walther et al. 2010). We calculated total soil carbon (C)

257 storage after correcting its content for soil depth, stone content and density of fine earth (see below).
258 Exchangeable cations were determined on another 5 g dry soil sample with 50 mL unbuffered 1 M NH₄Cl
259 solution (soil:solution ratio=1:10, end-over-end shaker for 1.5 hours) and measured by an ICP-OES
260 (Optima 7300 DV, Perkin-Elmer, Waltham, Massachusetts, USA). Thereafter, cation exchange capacity
261 (CEC) was calculated as the sum of exchangeable cations and protons (and expressed as mmol_c per 1 kg
262 soil) and used to describe nutrient retention capacity in our plots. Concentrations of exchangeable protons
263 were calculated as the difference between total and Al-induced exchangeable acidity as determined by the
264 KCl-method (Thomas 1982).

265 Ammonium (NH₄⁺) and nitrate (NO₃⁻) were extracted from a 20 g fresh subsample with 80 mL 1M
266 KCl for 1.5 hours on an end-over-end shaker and filtered through ashless folded filter paper (DF 5895
267 150, ALBET LabScience, Hahnemühle FineArt GmbH, Dassel, Germany). NH₄⁺ concentrations were
268 determined colorimetrically by automated flow injection analysis (FIAS 300, Perkin-Elmer, Waltham,
269 Massachusetts, USA). NO₃⁻ concentrations were measured colorimetrically according to Norman and
270 Stucki (1981). Potential soil net nitrogen (N) mineralization was assessed during an 8-week incubation
271 period under controlled moisture (60% of field capacity, see below), temperature (20 °C) and light
272 conditions (dark) in the laboratory. We weighed duplicate samples of fresh soil equivalent to 8 g dry soil
273 (24 h at 104 °C) into 50 mL Falcon tubes. Soil samples were extracted for NH₄⁺ and NO₃⁻ at the
274 beginning and after eight weeks as described above. Soil net N mineralization was calculated as the
275 difference between the inorganic nitrogen (NH₄⁺ and NO₃⁻) before and after the incubation (Hart et al.
276 1994), corrected for the total incubation time and represented per day values expressed as mg N kg⁻¹ soil
277 d⁻¹.

278 To assess soil physical properties, we randomly collected one undisturbed soil core per 4 m² subplot (5
279 cm diameter, 12 cm depth) in a steel cylinder that fit into the slide hammer (AMS Samplers, American
280 Falls, Idaho, USA). The cylinder was capped in the field to avoid disturbance. We then measured field
281 capacity in the laboratory. For this purpose, the cylinder and soil therein were saturated in a water bath
282 and drained on a sand/silt-bed with a suction corresponding to 60 cm hydrostatic head. The moist soil was

283 dried at 105 °C to constant weight. Field capacity was calculated by dividing the mass of water by the
284 total mass of wet soil contained at 60 cm hydrostatic head and used to describe water holding capacity.
285 Thereafter, samples were passed through a 4 mm mesh. Fine-earth and skeleton fractions were weighed
286 separately to assess bulk soil density (fine-earth plus skeleton), density of fine earth, and proportion of
287 skeleton. Particle density was determined with the pycnometer method (Blake and Hartge 1986), and total
288 porosity and proportion of fine pores were calculated (Danielson and Sutherland 1986). Clay, silt, and
289 sand contents were quantified with the sediment method (Gee and Bauder 1986).

290 Surface and soil temperature (12 cm depth, water-resistant digital pocket thermometer; IP65, H-B
291 Instrument, Trappe, Pennsylvania, USA) as well as volumetric soil moisture content (12 cm depth, time
292 domain reflectometry; Field-Scout TDR 300, Spectrum Technologies, Aurora, Illinois, USA) were
293 measured at five random locations within the 4 m² subplots every month from June to September. We
294 calculated the standard deviation of each temperature and moisture measure over four months to describe
295 seasonal variations. Slope inclination was determined at plot-level via GPS measurements (GPS 1200,
296 Leica Geosystem, Heerbrugg, Switzerland) and categorized into slope gradient classes according to FAO
297 standards (1990). Thickness of the topsoil horizon (equivalent to Ah or Aa horizon) was determined at
298 one soil monolith (30 x 30 x 30 cm³) per 4 m² subplot in cm and rounded to next integer.

299

300 **Ecosystem properties and multifunctionality (Research question 1 - 3)**

301 In total, we used 13 ecosystem properties that represented four major ecosystem attributes, namely
302 biodiversity (plant species richness, aboveground arthropod richness, belowground taxon richness),
303 structural diversity (vegetation structure, soil heterogeneity, above- and belowground functional diversity,
304 above- and belowground food-web complexity), soil functions (soil C storage, water holding capacity,
305 nutrient retention capacity), and soil processes (soil net N mineralization, Appendix S1: Table S2).

306 Selection of the 13 properties was based on suggested international principles and standards on
307 ecological restoration of the Society for Ecological Restoration (SER), and thus, included standardized
308 indicators of restoration success (McDonald et al. 2016, Gann et al. 2019). We used individual properties

309 that were shown to increase ecosystem functioning and invasion resistance, i.e. ecosystem stability, two
310 major goals in ecological restoration (details on rationales see Appendix S1: Table S2). Thus, we assumed
311 that restoring these properties and increasing their values is mandatory to meet the primary objective of a
312 restoration project, namely restoring high levels of ecosystem functioning and strengthening of ecosystem
313 stability (Gann et al. 2019).

314 Soil heterogeneity was calculated based on 20 soil properties (soil pH, organic C content, NO_3^- and
315 NH_4^+ concentrations, concentrations of exchangeable cations [Ca, K, Mg, Na, Mn], bulk density, texture,
316 proportion of skeleton and fine pores, thickness of topsoil horizon, slope class, seasonal variation in
317 surface and soil temperature as well as soil moisture). We z-transformed the 20 properties and then
318 calculated multivariate Euclidean distances for all pairwise between- and within-group combinations for
319 each treatment. We then used differences in group homogeneities based on group dispersion variances,
320 i.e., distance of single plot to its corresponding group centroid to obtain soil heterogeneity (betadisper
321 function of the vegan package, Oksanen et al. 2019, Alsterberg et al. 2017).

322 We calculated functional diversity for plants using shoot biomass of plant functional groups and for
323 faunal and microbial communities by assigning all taxonomic levels to functional groups. In total, 46
324 functional groups were defined based on lowest taxonomic resolution for each biotic community (see
325 Appendix S1: Table S3; Data repository: <https://doi.org/10.16904/envidat.169>). We calculated
326 multivariate Euclidean distances on z-transformed functional groups (relative abundances) for all pairwise
327 combinations of treatments and defined functional diversity above- and belowground using differences in
328 group homogeneities based on group dispersion variances.

329 Food-web complexity for faunal and microbial functional groups was based on life-history traits. For
330 each functional group we assigned: 1) feeding type, 2) trophic level, and 3) sensitivity to stress and/or
331 disturbance and recolonization ability (SD level), based on well-established bioindicative methods
332 (Bongers 1990, Parisi et al. 2005). For this study, we extended these methods to also address aboveground
333 arthropods, earthworms, prokaryotes and fungi. The ecomorphological index concept of soil
334 microarthropods (Parisi et al. 2005) was adopted for aboveground arthropods. For earthworms, we ranked

335 the sensitivity according to the r- and K-strategy (Römbke et al. 2005): sensitivity was ranked lowest for
336 epigeic species (one), followed by endogeic (five) and highest for anecic species (nine). The prokaryotic
337 community was classified based on copiotrophic-oligotrophic characteristic (for a review see Ho et al.
338 2017): copiotrophic and undefined bacteria received lowest (one), oligotrophic bacteria highest (nine)
339 rank. The fungal community was ranked based on the copiotrophic-oligotrophic concept only if known
340 (for a review also see Ho et al. 2017): copiotrophic saprotrophs, pathotrophs (excluding animal) and
341 undefined fungi were ranked lowest (one); symbiotrophs, biotrophs, animal pathogens and oligotrophic
342 saprotrophs received highest ranking (nine); saprotrophs (excluding oligo- or copiotrophs) and others
343 received an intermediate ranking (five). We then defined the trait-based factor as follows: 1) the digit
344 before the comma was defined by the feeding type and trophic level (ranging from one to five), 2) the
345 digit after the comma corresponded to stress/disturbance sensitivity and recolonization ability (ranging
346 from 1 to 9). Higher values of the trait-based factor indicated higher food-web complexity (see Appendix
347 S1: Table S3). We calculated weighted abundance per functional group by multiplying relative abundance
348 per functional group with its corresponding trait-based factor. Thereafter, food-web complexity was
349 defined as the standardized community weighted mean for the above- and belowground communities
350 separately.

351 We calculated five different multifunctionality measures using the averaging approach (Hooper and
352 Vitousek 1998). Ecosystem multifunctionality included all 13 ecosystem properties. We also calculated
353 aboveground multifunctionality (plant richness and vegetation structure, aboveground arthropod richness,
354 functional diversity, food-web complexity), belowground multifunctionality (belowground taxon
355 richness, functional diversity, food-web complexity, soil heterogeneity, soil C storage, water holding
356 capacity, nutrient retention capacity, soil net N mineralization), biotic multifunctionality (aboveground
357 arthropod richness, belowground taxon richness, plant richness, vegetation structure, above- and
358 belowground functional diversity, food-web complexity), and abiotic multifunctionality (soil
359 heterogeneity, soil C storage, water holding capacity, nutrient retention capacity and soil net N
360 mineralization). We did not use the threshold approach (Gamfeldt et al. 2008) as we were not interested in

361 assessing the number of properties performing above a certain threshold, but comparing levels of
362 multifunctionality in restored systems with those of our targeted semi-natural grasslands. The availability
363 of a real-world target rather than any arbitrarily chosen threshold justifies the use of the averaging
364 approach (Byrnes et al. 2014, Gamfeldt and Roger 2017).

365 All five multifunctionality measures were calculated after standardizing each ecosystem property
366 (Delgado-Baquerizo et al. 2019). For belowground taxon richness, functional diversity and food-web
367 complexity, standardization was applied within each faunal and microbial group before averaging to
368 counteract overrepresentation of microbial taxa. All ecosystem properties were weighted equally for
369 multifunctionality calculations. Potential collinearity between all pairs of individual ecosystem properties
370 was assessed using Pearson correlations to ensure that no highly correlated variables ($r > |0.7|$) were
371 included, and that no opposing performance (i.e., strong negative correlations) among the individual
372 ecosystem properties was present (Dormann et al. 2013; Appendix S1: Fig. S1).

373 Treatment differences (explanatory variable) in multifunctionality measures and the 13 ecosystem
374 properties (dependent variables) were assessed using beta regression on standardized values (Ferrari and
375 Cribari-Neto 2004). As beta regression models do only allow for values between 0 and 1 but not both
376 extremes (relevant only for individual properties), we transformed our data accordingly (Smithson and
377 Verkuilen 2006). Significant differences between treatments were identified using likelihood ratio tests
378 (lrtest function of the lmtest R package, Zeileis and Hothorn 2002). Post-hoc pairwise comparisons were
379 adjusted for multiple testing using the Bonferroni correction-method in combination with the false
380 discovery rate approach (cld function of the multcomp R package, Hothorn et al. 2008).

381

382 **Most cost-effective ways to describe multifunctionality (Research question 4)**

383 We assessed which ecosystem property or which combination of ecosystem properties explained the
384 highest amount of ecosystem multifunctionality at the lowest possible costs. For this purpose we
385 calculated 8190 alternative models using linear regression as implemented in an exhaustive search
386 approach (regsubsets function of the leaps R package, Lumley 2020). These models contained all possible

387 combinations of 13 ecosystem properties, hence we obtained a series of models that included 12
388 properties (all in EMF.12), a series of models that included 11 properties (EMF.11) and so forth
389 (Appendix S2). In a first step, we compared how much variation of ecosystem multifunctionality each of
390 these alternative models explained, using the Bayesian information criterion ($\Delta\text{BIC} > 2$, Table 1,
391 Kassambra 2018). We then selected the best models with 12, 11, 10, etc. variables.

392 We estimated costs to each ecosystem property by approximating costs for effort, infrastructure and
393 expert knowledge that are necessary to collect each of our 13 ecosystem properties (Appendix S1: Table
394 S4-S7). Costs were classified into coarse categories, represented by pluses (+) and where higher costs
395 equated to more +. We then assigned these costs to each alternative model described above by summing
396 the costs of all ecosystem properties included in the respective models (Appendix S2). We selected the
397 models with 12, 11, 10, etc. variables with the lowest costs (Table 2). Thus, we were able to evaluate how
398 much an alternative model explained and how much it would roughly cost to collect the data contained in
399 it.

400 All statistical analyses and graphical outputs were performed in R version 3.6.0 (R Core Team 2019).
401 A full list of all packages used can be found in Appendix S1: Table S8.

402 RESULTS

403 Ecosystem multifunctionality was higher in all three restored treatments than in *Initial*, but only
404 *Topsoil* and *Topsoil+Propagules* reached *Target* levels (Fig. 1A). Treatment differences in ecosystem
405 multifunctionality were mainly associated to differences in aboveground (Fig. 1B) and biotic (Fig. 1D)
406 multifunctionality, with the two topsoil removal treatments reaching higher levels than *Harvest only*.
407 Interestingly, the two topsoil removal treatments resulted in even higher aboveground and biotic
408 multifunctionality than *Target* (Fig. 1B, 1D). Belowground (Fig. 1C) as well as abiotic (Fig. 1E)
409 multifunctionality did not differ among the three restoration methods, but were significantly higher than
410 in *Initial* and significantly lower than in *Target* (exception: belowground multifunctionality in *Topsoil*).
411 Aboveground, belowground, biotic and abiotic multifunctionality were positively correlated with
412 ecosystem multifunctionality (Appendix S1: Figs. S2A-D).

413 Six out of the 13 ecosystem properties contributed significantly to both explaining ecosystem
414 multifunctionality and discriminating among the five treatments: Plant species richness, vegetation
415 structure, belowground functional diversity, aboveground food-web complexity, soil C storage, and soil
416 net N mineralization (Fig. 2, Table 1).

417 Including more variables into our model explained more variation in ecosystem multifunctionality.
418 Yet, naturally, this also increases the costs of collecting the data. The model including all 13 ecosystem
419 properties equals 100% ecosystem multifunctionality and would cost the most (77+). Interestingly, we
420 found negative relationships between explained variation in ecosystem multifunctionality and costs for
421 each group of models that included the same number of variables (Fig. 3). This means, low-cost measures
422 explained relatively more variation of ecosystem multifunctionality compared to high-cost measures
423 within a model cluster (Fig. 3, Table 1 and 2). Models with two or more properties included were able to
424 explain $\geq 70\%$ of ecosystem multifunctionality, however, the costs were 10+ and up (Table 2). The
425 “cheapest” model was based on vegetation structure (1+), but explained only 47.7% of ecosystem
426 multifunctionality (Table 1). Plant species richness accounted for 52.9% of ecosystem multifunctionality

427 at roughly 4 % (3+) of the cost of the model including all 13 properties (77+) and represented the best
428 individual indicator of all 13 ecosystem properties (Table 1). Plant species richness, in addition,
429 discriminated significantly among the treatments (Fig. 2, Table 1).

430 Vegetation structure, soil C storage and water holding capacity together explained 70% of ecosystem
431 multifunctionality at the costs of roughly 8% (6+) of what it took to obtain all 13 variables. On the
432 contrary, by using vegetation structure, soil C storage and water holding capacity we increased the costs
433 by roughly 17% compared to when we only used vegetation structure alone, but we gained 22.3% of
434 explained variation of ecosystem multifunctionality (Table 1). Hence, this model can be considered the
435 most cost-effective while describing a high amount of ecosystem multifunctionality (Table 2).

436 **DISCUSSION**

437 **Restoring grassland multifunctionality**

438 Ecosystem multifunctionality was significantly higher in semi-natural grasslands compared to
439 intensively managed grasslands (research question 1). This is in line with studies showing that intensive
440 agriculture decreases multifunctionality by homogenizing plant and faunal communities and soil
441 properties (e.g., Birkhofer et al. 2012, Gossner et al. 2016, Soliveres et al. 2016), and reducing functional
442 diversity at local and landscape scales (Allan et al. 2015, Neff et al. 2019). In contrast, traditionally
443 managed semi-natural grasslands are characterized by high taxonomic and structural heterogeneity above-
444 and belowground (Lachat et al. 2010, Diacon-Bolli et al. 2012, Byrne and delBarco-Trillo 2019, Peciña et
445 al. 2019), thereby supporting multiple functions and services simultaneously.

446 For all three restoration methods we found higher ecosystem multifunctionality than in intensively
447 managed grasslands, but only the two topsoil removal treatments reached *Target* levels within 22 years
448 (research question 2). Thus, these restoration methods allow rebuilding multifunctionality comparable to
449 the targeted semi-natural grasslands over decadal time frames, which has already been reported from
450 peatlands (Strobl et al. 2019). We also provide strong evidence that topsoil removal not only promoted the
451 restoration of grassland multifunctionality, but also successfully re-established ecosystem
452 multifunctionality comparable to the targeted semi-natural grasslands. Similar results have been reported
453 for Mediterranean forests, where the long-term recovery of forest multifunctionality depended on the
454 intervention intensity of the restoration methods used (natural regeneration vs. active planting, Cruz-
455 Alonso et al. 2019).

456 We assessed 13 different biotic and abiotic, above- and belowground ecosystem properties that
457 represented key attributes of the targeted ecosystem. We specifically focused on integrating belowground
458 ecosystem properties and functions as their recovery during restoration has been suggested essential for
459 evaluation (see Bardgett et al. 2005, Meyer et al. 2015), especially for restoration methods that strongly
460 affect the soil, such as topsoil removal. This comprehensive assessment allowed us to also identify the

461 contribution of the different ecosystem components to multifunctionality of restored grasslands (research
462 question 3). Thereby, we demonstrated that topsoil removal clearly accelerated the recovery of biotic and
463 aboveground multifunctionality while it had no negative long-term effects on abiotic or belowground
464 multifunctionality compared to low intervention methods. Topsoil removal even led to a higher biotic
465 multifunctionality compared to the *Target*, indicating that our measures succeeded in creating species-rich
466 and functional systems, which are, however, slightly different from our *Target* sites. Furthermore, our
467 results also revealed that abiotic multifunctionality in all three restoration methods did not reach target
468 levels, even 22 years after treatment implementation. Thus, the long-term recovery of abiotic soil
469 properties lags behind aboveground properties. This is in line with short-term studies reporting time lags
470 in the response of biotic aboveground and belowground communities to changed soil conditions (see
471 Bardgett et al. 2005, Kardol et al. 2005, 2009a). The apparent failure in recreating soils with an equivalent
472 level of abiotic multifunctionality compared to target systems, therefore, underlines that protection and
473 conservation efforts are most urgently needed to minimize degradation and loss of biodiversity and
474 ecosystem functioning (e.g., United Nations 2015: Sustainable Development Goal 15, Pe'er et al. 2020).

475 Although particular standards for ecological restoration urged the need for comprehensive assessments
476 (see Gann et al. 2019), long-term multifunctionality studies in grassland ecosystems have so far been
477 lacking. In addition, studies assessing the long-term recovery of multiple biotic and abiotic belowground
478 properties after topsoil removal are scarce and primarily focused on individual properties (e.g., Frouz et
479 al. 2009, Wubs et al. 2016, Resch et al. 2019). Here we show that long-term studies that incorporate
480 multiple above- and belowground ecosystem components are important as the evaluation of restoration
481 success strongly depends on the number and identity of the indicators used (e.g., Montoya et al. 2012,
482 Wortley et al. 2013). Thus, we strongly recommend to integrate biotic and abiotic, above- and
483 belowground properties in long-term monitoring programs to appropriately represent the entire
484 ecosystem.

485

486 **Revealing ecosystem multifunctionality in a most cost-efficient way**

487 We used 13 ecosystem properties to calculate ecosystem multifunctionality, which was highly
488 resource-intensive. Monitoring the success of restoration projects is normally resource-limited, only
489 allowing for the collection of a restricted set of properties (Montoya et al. 2012, Gann et al. 2019). To
490 explore which of our 13 properties (alone or in combination) would be best suited to describe ecosystem
491 multifunctionality with relative high accuracy, but at low costs, we conducted a “cost-benefit analysis”
492 (research question 4). Plant species richness was found to be the most accurate individual indicator
493 successfully describing ecosystem multifunctionality (52.9 %), which supports its supremacy as the most
494 commonly used biotic indicator for conservation agencies conducting such restoration monitoring (Kiehl
495 et al. 2010). Vegetation structure would be the cheapest individual property, but still described quite a
496 high amount of ecosystem multifunctionality (47.7 %), hence, could be used instead of plant species
497 richness if funding is limited or experts are scarce, but long-term restoration monitoring is stipulated by
498 statutory regulations. However, vegetation structure complemented with two low-cost belowground
499 properties, i.e. soil C storage and water holding capacity, would allow for a highly cost-effective
500 monitoring of ecosystem multifunctionality. Such a combination provides land managers or nature
501 protection agencies with an accurate measure to monitor how ecosystem multifunctionality is restored
502 over decadal time frames.

503 CONCLUSIONS

504 Long-term monitoring of restoration projects is indispensable to implement adaptive management
505 strategies if necessary and assess restoration success. This is of major importance for industries (e.g.,
506 mining companies), governments, communities and land managers ultimately responsible for
507 implementing enforced statutory regulations and the subsequent evaluation of restoration activities in the
508 long-term. Practical standards to monitor and evaluate restoration have already been proposed.
509 Nevertheless, long-term studies combining aboveground and belowground ecosystem multifunctionality
510 assessments to evaluate the recovery of targeted ecosystem properties were lacking. Therefore, the
511 findings of our study can serve as a guideline to monitor and evaluate long-term grassland restoration,
512 using a comprehensive, multifunctional approach.

513 In the advent of the United Nations Decade on Ecosystem Restoration (2021-2030) multiple priorities
514 need to be set to foster the cumulative gains of restoration actions across the globe. Hence, new
515 restoration initiatives should not only focus on defining which specific types of ecosystems or global
516 regions should be prioritized for restoration activities, but also on promoting and implementing cost-
517 efficient properties to accurately assess entire ecosystems and their recovery following restoration. In this
518 study, we showed that for our grassland systems assessing vegetation structure, soil C storage and water
519 holding capacity allows for a highly cost-effective long-term monitoring of ecosystem multifunctionality.
520 As this is one of the first studies considering a multifunctionality approach, further evidence from other
521 ecosystems is needed to validate the generality of our results. Nevertheless, we are highly confident that
522 our findings can serve as a baseline to help overcome funding limitations within restoration projects, often
523 prevalent in less developed countries where restoration activities are especially needed.

524 **ACKNOWLEDGEMENTS**

525 We thank Matthias Diener, Njoku Nwawudu, Anja Marty and Martin Gossner for help in sampling
526 and sorting of invertebrates as well as laboratory work on soil properties; Benjamin Fitzpatrick for
527 suggestions regarding statistical methods; the Genetic Diversity Centre (GDC) of ETH Zurich for
528 suggestions regarding analyzing molecular data; and Roel Wagenaar, Roger Köchli, Daniel Christen,
529 Marco Walser, and Beat Stierli for technical assistance. We also thank the Nature Conservation Agency
530 of Canton Zurich, under the supervision of Pascale Weber and Ursina Wiedmer, for administrative
531 support with farmers, regional commissioners for nature conservation and access permits for the
532 respective nature reserves. This work was supported by the Swiss National Science Foundation (grant
533 number 31003A_166654).

534

535 **AUTHORS' CONTRIBUTIONS**

536 MCR, ACR, MS, BF, SZ, and NB designed the experiment; MCR, ACR and MS developed the ideas
537 for the manuscript; MCR, SZ and UG collected the data; WHvdP, BF and SZ led the lab work; MCR
538 analyzed the data and wrote the first draft of the paper; ACR and MS commented on all drafts of the
539 paper; NB, BF, UG, SZ and WHvdP contributed critically to the advanced drafts of the paper; all authors
540 gave final approval for publication.

541

542 **DATA ACCESSIBILITY**

543 Data available via the EnviDat Repository <https://doi.org/10.16904/envidat.169>. Raw sequences of the
544 soil microbial community are deposited in the NCBI Sequence Read Archive under the BioProject
545 accession number PRJNA630536.

824 **TABLES**

825 **Table 1.** Statistical analyses for all 13 ecosystem properties that we used to calculate ecosystem
 826 multifunctionality, and to discriminate among our restored, intensively managed and semi-natural
 827 grasslands (overall, pairwise comparison). Model comparison was based on the explained variation of
 828 ecosystem multifunctionality (r^2) and on the Bayesian information criterion (BIC). Ecosystem properties
 829 are sorted by ecosystem attribute and consecutively numbered (No.). Cost = cost categorization according
 830 to effort, infrastructure and expert knowledge needed for assessment (see Appendix S1: Table S4); r^2 =
 831 Pseudo r^2 ; χ^2 = Chi squared value; ΔBIC = difference in BIC units to the lowest ranked property (lowest
 832 BIC = plant species richness); I = *Initial*; H = *Harvest only*; Ts = *Topsoil*; TsP = *Topsoil+Propagules*; T =
 833 *Target*; AG = aboveground; BG = belowground. Different lower case letters indicate significant differences
 834 between treatments.

Ecosystem attribute	Ecosystem property	Ecosystem multifunctionality				Treatment

835

836 **Table 2.** Comparison of top alternative models based on highest explained variation of ecosystem
 837 multifunctionality (EMF) or lowest cost. Alternative ecosystem multifunctionality models were clustered
 838 according to the number of ecosystem properties included in the calculations (EMF.1-12). Alternative
 839 models for highest explanatory power were compared based on the Bayesian information criteria (BIC)
 840 and considered different when the difference in ΔBIC was > 2 (Kassambra 2018; Appendix S2). This was
 841 done for each cluster separately. % EMF = proportion of ecosystem multifunctionality explained; Cost =
 842 total costs for a specific model (Table 1; Appendix S1: Table S4; Appendix S2); Properties considered =
 843 List of ecosystem properties included, numbers correspond to Table 1 (No.).

EMF model	highest explanatory power			lowest cost

845 FIGURE LEGENDS

846 **Fig. 1.** Treatment effects on ecosystem (A), aboveground (B), belowground (C), biotic (D) and abiotic
847 (E) multifunctionality (mean \pm SE). All five multifunctionality measures represent weighted average values
848 of standardized properties (y-axis: scaled between 0 and 1). Different lower-case letters indicate significant
849 differences between treatments. I = *Initial*; H = *Harvest only*; Ts = *Topsoil*; TsP = *Topsoil+Propagules*; T
850 = *Target*.

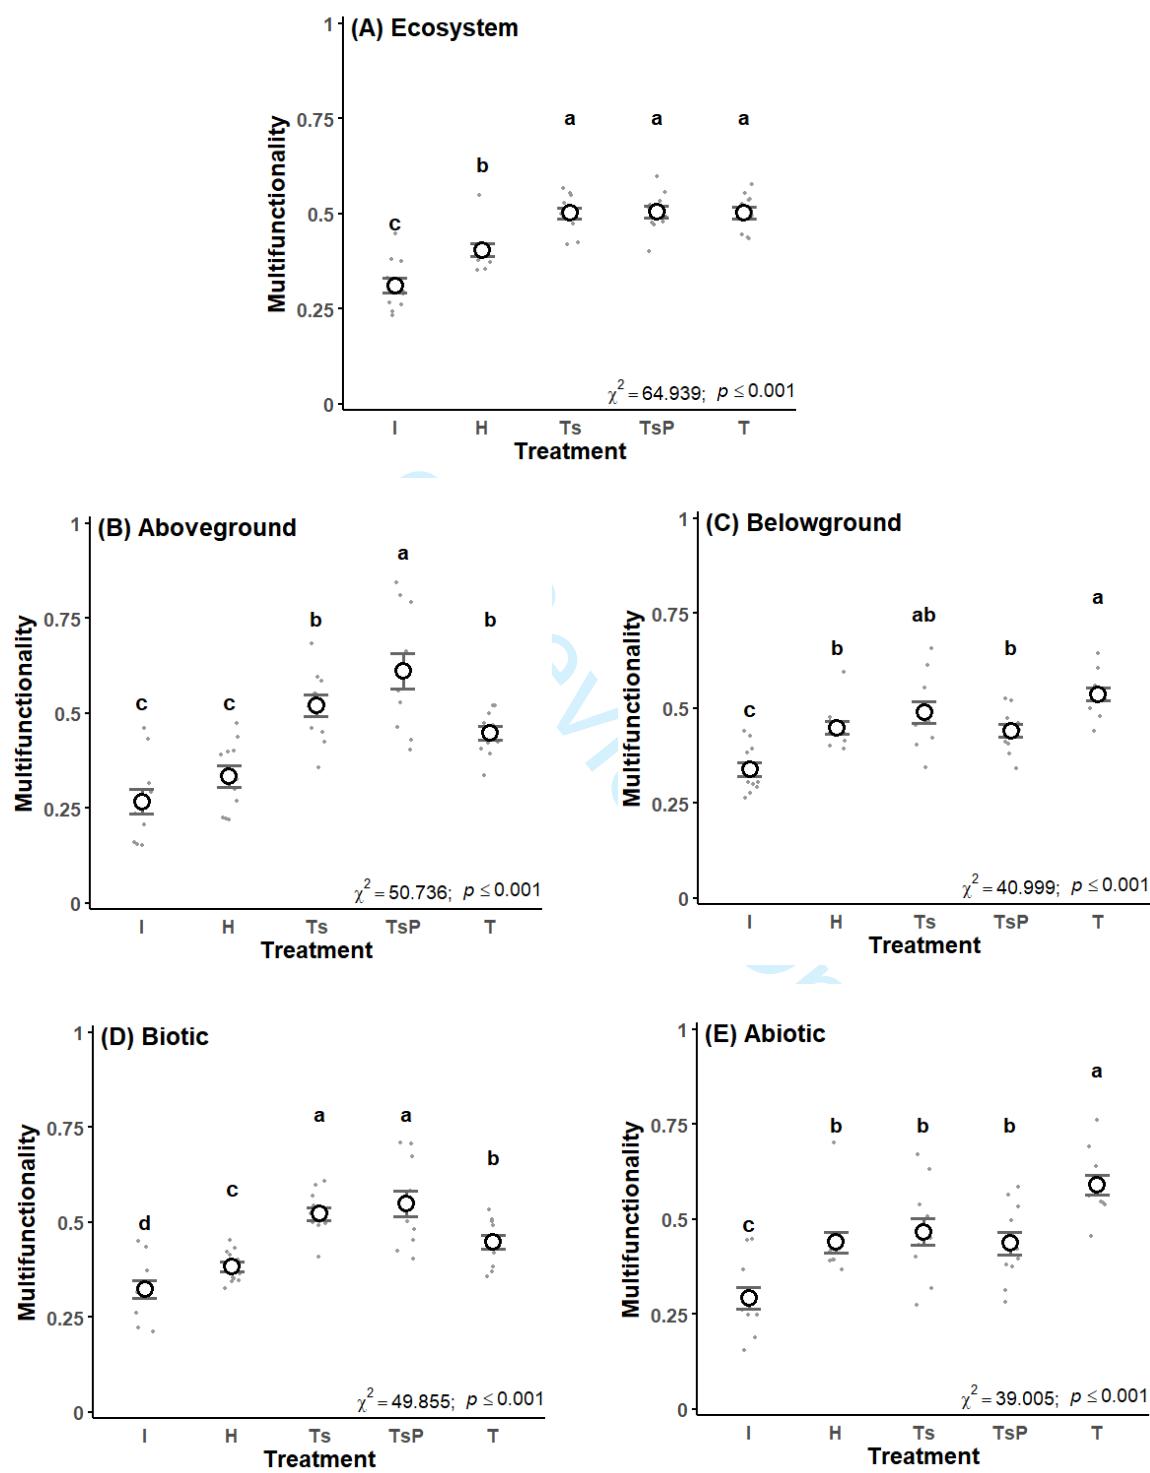

851

852 **Fig. 2.** Treatment effects on standardized ecosystem properties (mean \pm SE; 1-13). Different lower case
853 letters indicate significant differences between treatments. AG = aboveground; BG = belowground; I =
854 *Initial*; H = *Harvest only*; Ts = *Topsoil*; TsP = *Topsoil+Propagules*; T = *Target*. Label numbers refer to
855 Table 1 (No.).

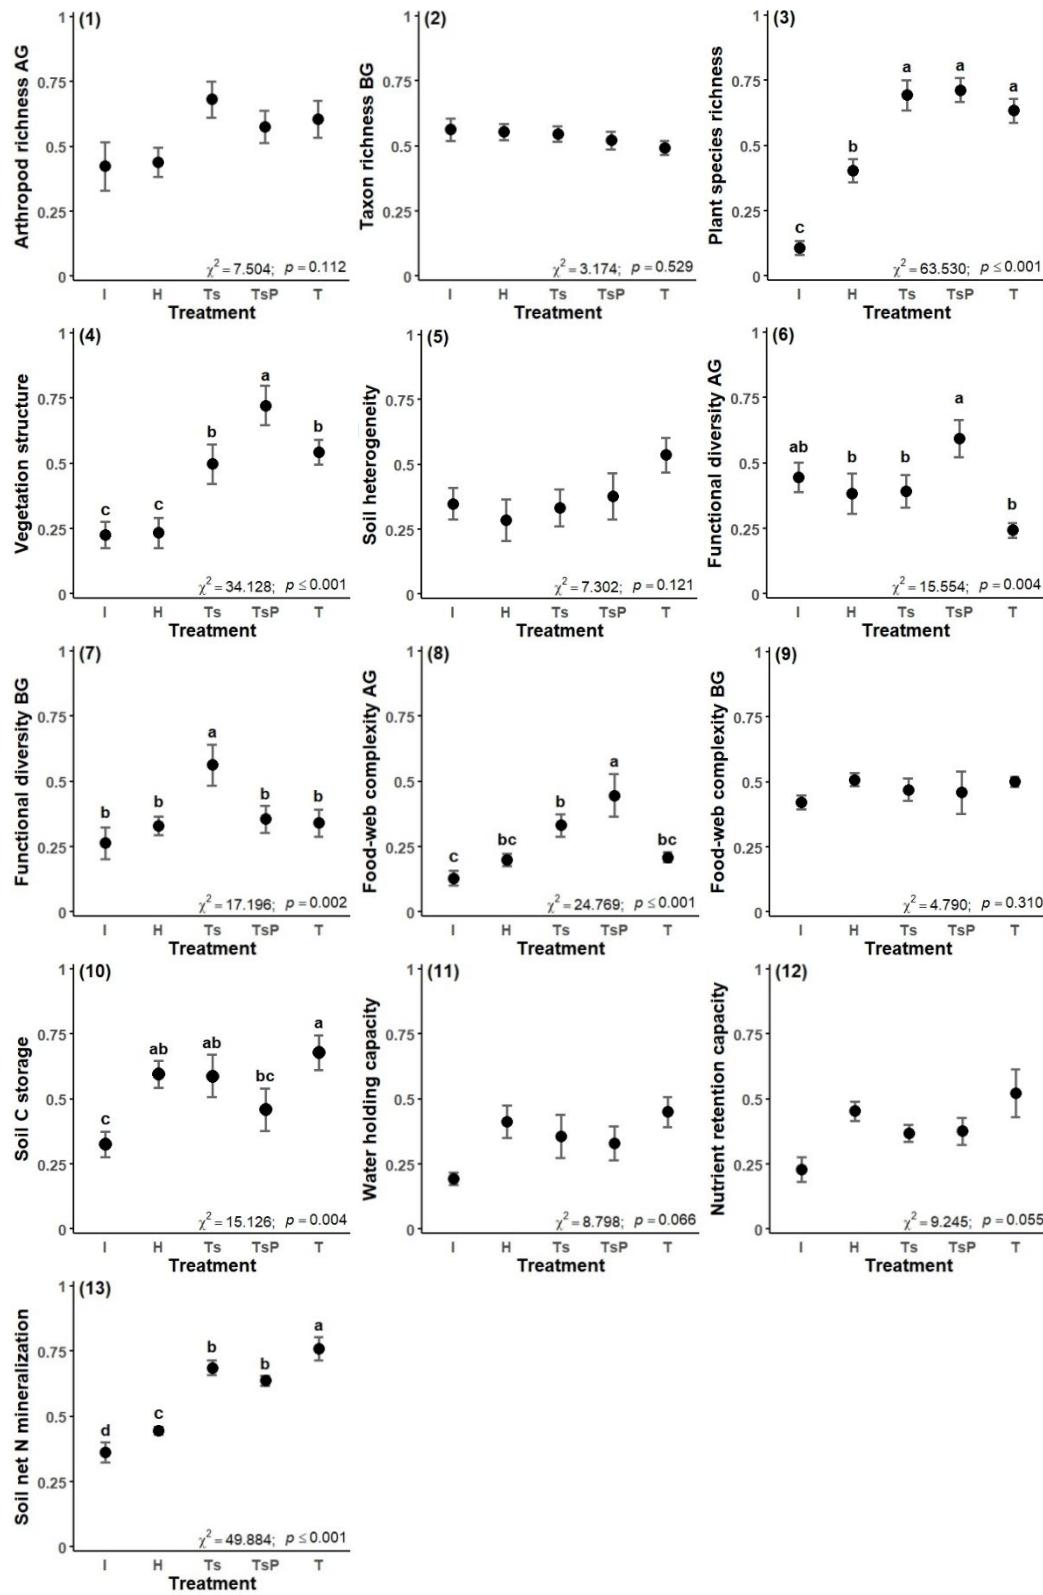

856

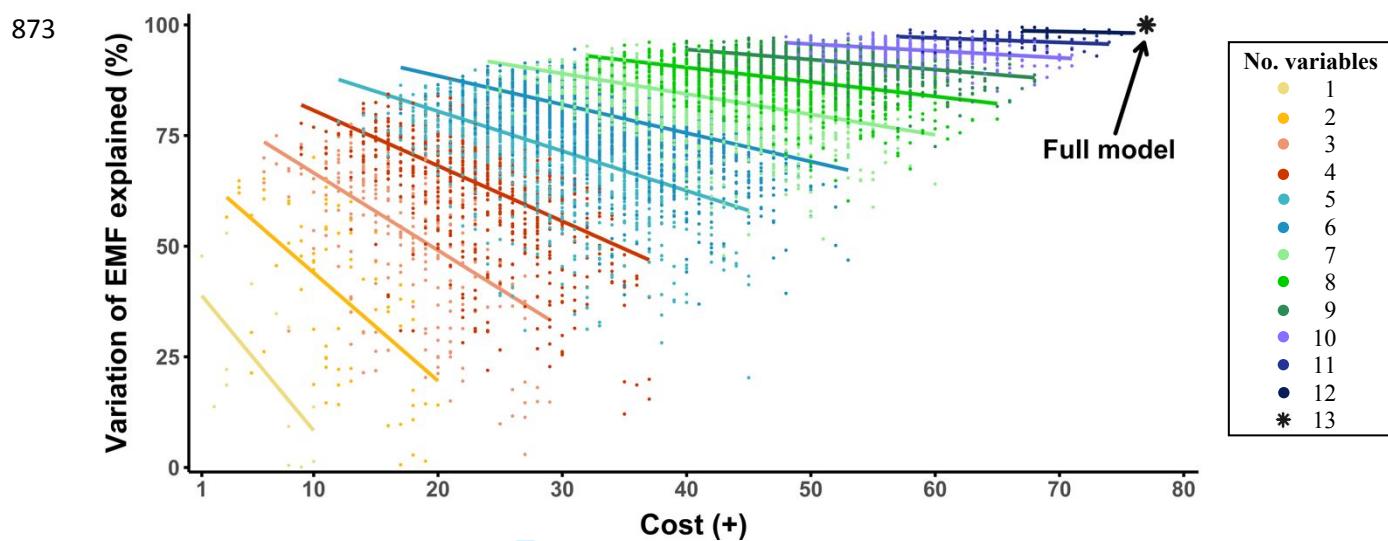

857 **Fig. 3.** Relationship of explained variation of ecosystem multifunctionality (EMF) with costs for
858 individual and multiple ecosystem properties. Subsets of possible combinations were identified by the
859 stepwise reduction of all 13 ecosystem properties using an exhaustive search approach, which resulted in
860 8190 alternative calculations of ecosystem multifunctionality (single points; Appendix S2). Alternative
861 calculations of ecosystem multifunctionality were clustered by number of included ecosystem properties
862 (No. variables) and indicated by different colors. Linear regressions were calculated per cluster and also
863 indicated in the respective colors. For comparison, ecosystem multifunctionality calculated based on all 13
864 properties and the respective costs are also shown (* = Full model).

For Review Only

17 **Figure S1:** Scatterplot matrix for pair-wise comparison of the 13 ecosystem properties using Pearson
 18 correlations. Strength of correlation is size-coded (increasing font size=higher correlation). No highly
 19 correlated variables, i.e. Pearson $> |0.7|$, were identified, therefore all ecosystem properties were kept
 20 for further multifunctionality calculations (Dormann et al. 2013). Ri = richness; AG = aboveground;
 21 BG = belowground; Veg.str = vegetation structure; Soil.het = soil heterogeneity; FD = functional
 22 diversity; FW = food-web complexity; C.stor = soil carbon storage; H2O.cap = water holding
 23 capacity; Nut.ret = nutrient retention capacity; N.min = soil net nitrogen mineralization.

24

25

26 **Figure S2:** Relationship between ecosystem multifunctionality and aboveground (A), belowground
27 (B), biotic (C), and abiotic (D) multifunctionality across all five treatments. Degrees of freedom:
28 numerator=1, denominator=53.

29 **Table S1:** Detailed site description of individual plots. Management: level of mowing frequency per
 30 year; for Initial plots = mowing frequency equivalent to manuring frequency (35-40 kg N ha⁻¹
 31 application-1). Tillage: last time the plot was tilled. Land-use: for Initial plots = recent agricultural
 32 use; for all restored sites = agricultural use before restoration; TG = temporary grassland; PG =
 33 permanent grassland. Mowing: for Initial plots = earliest date of biomass harvesting; for restored and
 34 target sites: earliest date(s) of biomass harvesting based on contracts between farmers and the Nature
 35 Protection Agency of Zurich. Soil type: Soil types based on soil mapping survey 1991 (before
 36 restoration). Slope: slope gradient classes in % according to FAO (1990).

Plot	Treatment	X Coordinate	Y Coordinate	Management	Tillage	Land use	Mowing	Soil type	Slope

38 **Table S2:** Ecosystem attributes, their ecological importance, and their link to selected ecosystem
 39 properties. AG = aboveground; BG = belowground.

Ecosystem attribute	Important indications	Ecosystem property	References
Biodiversity	- Ecosystem stability, resistance and resilience: ability to counteract or buffer environmental changes (e.g. climatic extremes such as droughts or floods); increases rates and pace of recovery from disturbance; acts as barrier to ecological invasion	Arthropod richness AG Taxon richness BG Plant richness	Pennekamp et al. 2018; Isbell et al. 2015; Kennedy et al. 2002; Naeem et al. 2000
Structural diversity	- Niche availability and differentiation: vertical stratification influences important habitat features (i.e., microclimate, food and shelter availability); increased heterogeneity promotes species coexistence and hence species diversity - Spatial heterogeneity: increased patchiness of resources promotes niche differentiation and counteracts homogenization and dominance of exploitative species - Resource utilization efficiency: functional complementary or redundancy of organismic groups indicates sustainability or exploitation of resources; complementary or opposing effects due to enhanced diversity in functional groups	Vegetation structure Soil heterogeneity Functional diversity	Schuldt et al. 2019; Diacon-Bolli et al. 2012; Pacini et al. 2009; Tews et al. 2004 Baer et al. 2019; Gossner et al. 2016
Soil functions	- Presence and diversity of key trophic levels: indicator of disturbance intensity (e.g. restoration method, one-time) or management (ongoing); increased levels of disturbance decrease complexity by absence of higher trophic levels	Food-web complexity	Oliveres et al. 2016; Vandewalle et al. 2010; Pacini et al. 2009; Yachi and Loreau 2007; Rosenfeld 2002 Parisi et al. 2005; Bongers 1990
Soil process	- Water regulation: hydrological conditions (e.g., changes in groundwater level) and water availability for plant growth - Storage and filtering capacity: storing, filtering and transforming nutrients and pollutants; regulation of nutrient sequestration and flow to mitigate negative effects of land use or climate change - Soil fertility: capacity of soil to hold and exchange cations in a plant available form; reduced values indicate for potential threat of excessive nutrient-leaching or soil acidification - Nutrient cycling: appropriate levels of plant growth and productivity in sustainable and self-supporting ecosystems	Water holding capacity Soil carbon storage Nutrient retention capacity Soil net nitrogen mineralization	Hazelton and Murphy 2007; Delarze et al. 2015 Wang et al. 2019; Ward et al. 2016; Grêt-Regamey et al. 2016 Matson et al. 1997 Risch et al. 2018; Risch et al. 2019

41 **Table S3:** Classification of faunal and microbial functional groups according to which part of the
 42 ecosystem they inhabit (above-/belowground), phylum, identification level of taxonomic or functional
 43 group, feeding type, trophic level, response to increased stress or disturbance levels (SD level), and
 44 the proposed factor defining food-web complexity (FW factor, feeding type + trophic level + SD
 45 level). Classification of functional groups was based on lowest taxonomic resolution (see also Data
 46 repository: <https://doi.org/10.16904/envidat.169>). This information was used to assess functional
 47 diversity (feeding type + trophic level) and food-web complexity (rel. abundance multiplied by FW
 48 factor) above- and belowground. Collembola were classified into functional subgroups following
 49 Oliveira Filho et al. (2016). .a = adults; .l = larvae; .juv = juveniles; EMI = ecomorphological index
 50 (Parisi et al. 2005); SD = stress/disturbance level; C-P = colonizer-persister scaling (Bongers 1990).

Ecosystem	Phylum	Taxonomic unit/ compartment	Functional groups	Feeding type	Trophic level	SD level	FW factor

52 **Table S4:** Summarized cost categorization for the 13 ecosystem properties used to calculate
 53 multifunctionality measures. Effort: sampling, extraction and identification (i.e., time needed).
 54 Infrastructure: equipment (e.g., microscopes) and laboratories (e.g., wet, genetic). Analyses requiring
 55 specific equipment (e.g., sequencing machines, CN analyzer) for soil genetic and chemical properties,
 56 have been outsourced to specialized companies as might be most eligible for practical
 57 implementation. Expert knowledge: expertise for identification, classification and interpretation (e.g.,
 58 biotic communities). Categories were based on detailed assessment for effort, infrastructure and
 59 expert knowledge listed in Tables S5, S6 and S7. AG = aboveground; BG = belowground.

Ecosystem property	Cost	Effort	Infrastructure	Expert knowledge
1 Arthropod richness AG	7+	++++	+	++
2 Taxon richness BG	9+	++++	+++	++
3 Plant richness	3+	+		++
4 Vegetation structure	1+	+		
5 Soil heterogeneity	8+	++++	++	++
6 Functional diversity AG	8+	++++	+	+++
7 Functional diversity BG	10+	++++	+++	+++
8 Food-web complexity AG	8+	++++	+	+++
9 Food-web complexity BG	10+	++++	+++	+++
10 Soil carbon storage	2+	+	+	
11 Water holding capacity	3+	++	+	
12 Nutrient retention capacity	3+	++	+	
13 Soil net nitrogen mineralization	5+	++	++	+

61 **Table S5:** Detailed description of the effort needed to assess individual ecosystem properties in our
 62 specific study. Estimates are given as work days per sample for the different tasks to obtain raw data
 63 to be used in data analysis. AG = aboveground; BG = belowground.

Ecosystem property	Sampling + Extraction	Sorting + Identification	additional classification
1 Arthropod richness AG	1.0	5.0	---
2 Taxon richness BG			---
- earthworms	0.04	0.5	
- arthropods	7.0	2.0	
- nematodes	7.0	0.5	
- microbes	2.0	3.0	
3 Plant richness	---	0.04	---
4 Vegetation structure	0.02	---	---
5 Soil heterogeneity		---	---
- soil pH	1.0		
- organic C content	1.5		
- NO_3^- concentration	0.5		
- NH_4^+ concentration	0.5		
- exchangeable cation concentrations	0.5		
- bulk density	0.5		
- proportion of skeleton	1.0		
- texture	1.5		
- proportion of fine pores	0.2		
- thickness of topsoil horizon	0.02		
- slope class	0.02		
- seasonal variation surface temperature	0.5		
- seasonal variation soil temperature	0.5		
- seasonal variation soil moisture	0.5		
6 Functional diversity AG	see Arthropod richness AG		3.0
7 Functional diversity BG	see Taxon richness BG		1.0
8 Food-web complexity AG	see Arthropod richness AG		1.0
9 Food-web complexity BG	see Taxon richness BG		1.0
10 Soil carbon storage	1.0	---	---
11 Water holding capacity	see bulk density		1.0
12 Nutrient retention capacity	see exchangeable cations		1.0
13 Soil net nitrogen mineralization	see NO_3^- and NH_4^+		2.5

65 **Table S6:** Detailed description of the infrastructure needed to assess individual ecosystem properties.
 66 Infrastructure included the equipment and laboratories needed for the sample processing. AG =
 67 aboveground; BG = belowground.

Ecosystem property	Equipment	Laboratories
1 Arthropod richness AG	- suction sampler - binocular	- dry lab
2 Taxon richness BG	- soil hammer, spade - Oostenbrink elutriator (nematodes) - Berlese-Tullgren funnels (arthropods) - binocular (earthworms, arthropods) - microscope (nematodes) - centrifuge, shaker, scales, extractor hood - drying oven, refrigerator, freezer - PCR machines, spectral photometer, electrophoresis	- dry and wet labs - DNA extraction lab - PCR amplification lab - electrophoresis lab
3 Plant richness	---	---
4 Vegetation structure	---	---
5 Soil heterogeneity	- soil hammer, spade - centrifuge, shaker, scales, extractor hood - drying oven, refrigerator - water-resistant digital pocket thermometer - time domain reflectometer (TDR)	- dry and wet labs
6 Functional diversity AG	see Arthropod richness AG - shears, drying oven, scales (plant biomass)	
7 Functional diversity BG	see Taxon richness BG	
8 Food-web complexity AG	see Arthropod richness AG	
9 Food-web complexity BG	see Taxon richness BG	
10 Soil carbon storage	- soil hammer - drying oven - CN analyzer	- dry lab
11 Water holding capacity	- soil hammer - drying oven - water bath and sand/silt-bed drainage	- dry and wet labs
12 Nutrient retention capacity	- soil hammer - drying oven	- dry lab
13 Soil net nitrogen mineralization	- soil hammer - drying oven, refrigerator, climatic chambers	- dry and wet labs

69 **Table S7:** Detailed description of the area of expertise needed to assess individual ecosystem
70 properties. AG = aboveground; BG = belowground.

Ecosystem property	Area of expertise
1 Arthropod richness AG	- identification and classification of AG arthropods (order to family level)
2 Taxon richness BG	- identification and classification of earthworms (species level) - identification and classification of soil arthropods (order to family level) - identification and classification of soil nematodes (family level) - interpreting metabarcoding data of soil microbes (OTU level)
3 Plant richness	- identification and classification of plants (species level)
4 Vegetation structure	---
5 Soil heterogeneity	- soil chemical, physical, and biogeochemical analysis
6 Functional diversity AG	- see Arthropod richness AG - functional classification of plant species - functional classification of arthropod groups
7 Functional diversity BG	- see Taxon richness BG - functional classification of all biotic groups studied
8 Food-web complexity AG	- see Arthropod richness AG - functional classification of arthropod groups - classification according to taxon response to increased stress or disturbance levels (SD level)
9 Food-web complexity BG	- see Taxon richness BG - functional classification of all biotic groups studied - classification according to taxon response to increased stress or disturbance levels (SD level)
10 Soil carbon storage	---
11 Water holding capacity	---
12 Nutrient retention capacity	---
13 Soil net nitrogen mineralization	- soil chemical and biogeochemical analysis

71

72 **Table S8:** R libraries and packages used for analyses of ecosystem multifunctionality and its single
 73 components as well as individual ecosystem properties are listed, indicating reason of analyses.

Analyses	Package	Version	Citation

Evaluating long-term success in grassland restoration – an ecosystem multifunctionality approach.

Appendix S2: Supporting information on alternative ecosystem multifunctionality (EMF) models

Variable	Description
EMF.x.x	consecutively numbered alternative models after clustering models by number of included variables
EMF.x	series of alternative models grouped by the number of included variables (combination cluster)
No.	number of included variables in the respective alternative model
Ri.AG	Aboveground arthropod richness
Ri.BG	Belowground taxon richness (earthworms, arthropods, nematodes, fungi, prokaryotes)
Ri.Plant	Plant richness
Veg.str	Vegetation structure
Soil.het	Soil heterogeneity
FD.AG	Functional diversity aboveground (relative abundance of plant and faunal functional groups)
FD.BG	Functional diversity belowground (relative abundance of microbial and faunal functional groups)
FW.AG	Food-web complexity aboveground (standardized community weighted mean of abundance per functional group; life-history trait-based approach for faunal functional groups; trait-based factor reflects three aspects of food-web structure: 1) feeding type, 2) trophic level, and 3) sensitivity to stress and/or disturbance as well as recolonization ability ["SD level"])
FW.BG	Food-web complexity belowground (standardized community weighted mean of abundance per functional group; life-history trait-based approach for faunal and microbial functional groups; trait-based factor reflects three aspects of food-web structure: 1) feeding type, 2) trophic level, and 3) sensitivity to stress and/or disturbance as well as recolonization ability ["SD level"])
C.stor	Soil carbon storage (total soil carbon (C) content corrected for soil depth and density of fine earth)
H2O.cap	Water holding capacity (Field capacity at 60 cm hydrostatic head)
Nut.ret	Nutrient retention capacity (Cation exchange capacity [CEC]; mmolc per 1 kg soil)
N.min	Soil net nitrogen mineralization (mg N kg ⁻¹ soil d ⁻¹)
r2	Explained variation of overall EMF ("Pseudo r ² ")
BIC	Bayesian information criteria
ΔBIC.overall	Difference in BIC units to the lowest ranked model across all possible combinations
ΔBIC.cluster	Difference in BIC units to the lowest ranked model within series of alternative models (EMF.x)
Cost	Cost categorization according to effort, infrastructure and expert knowledge needed for assessment
best.r2	Highest explained variation of overall EMF at lowest Cost within combination cluster
best.cost	Lowest Cost at highest explained variation of overall EMF within combination cluster

21 ABSTRACT

22 It is generally assumed that restoring biodiversity will enhance diversity and ecosystem functioning.

23 However, to date, it has rarely been evaluated whether and how restoration efforts manage to rebuild

24 biodiversity and multiple ecosystem functions (ecosystem multifunctionality) simultaneously. Here, we

25 quantified how three restoration methods of increasing intervention intensity (harvest only < topsoil
removal < topsoil removal + propagule addition) affected grassland ecosystem multifunctionality 22 years

26 after the restoration event. We compared restored with intensively managed and targeted semi-natural

27 grasslands based on 13 biotic and abiotic, above- and belowground properties. We found that all three

28 restoration methods improved ecosystem multifunctionality compared to intensively managed grasslands

29 and developed towards the targeted semi-natural grasslands. However, whereas higher levels of

30 intervention intensity reached ecosystem multifunctionality of targeted semi-natural grasslands after 22

31 years, lower intervention missed this target. Moreover, we found that topsoil removal with and without
seed addition accelerated the recovery of biotic and aboveground properties, and we found no negative
long-term effects on abiotic or belowground properties despite removing the top layer of the soil. We also

32 evaluated which ecosystem properties were the best indicators for restoration success in terms of accuracy

33 and cost efficiency. The most accurate single property was plant species richness (53 % Overall, we
demonstrated that low-cost measures explained relatively more variation of ecosystem multifunctionality

34 explained) compared to high-cost measures. Plant species richness was the most accurate individual
property in describing ecosystem multifunctionality, as it accounted for 53% of ecosystem

35 multifunctionality at only 4-% of the costs of our comprehensive multifunctionality approach. This Plant
species richness is the property that typically is used in restoration monitoring schemes by conservation

36 agencies. Vegetation structure, soil carbon storage and water holding capacity together explained 70-% of

37 ecosystem multifunctionality at only twice the costs (8-% of plant species richness, which is, in our

38 opinion, worth considering in future restoration monitoring projects. Hence, our findings provide a

- 45 guideline for land managers how they could obtain an accurate estimate of aboveground-belowground
- 46 ecosystem multifunctionality and restoration success in a highly cost-efficient way.

54 INTRODUCTION

55 Semi-natural grasslands are an integral part of the Western and Central European cultural landscape
56 and result from traditional farming over centuries (Van Dijk 1991, Poschlod and Wallis De Vries 2002,
57 Bobbink et al. 2011). These grasslands are among the most species-rich ecosystems and represent
58 biodiversity hotspots that harbor specialized plant and animal communities with high numbers of rare and
59 endangered species (Dengler et al. 2014). Semi-natural grasslands are characterized by low productivity
60 and high structural heterogeneity with a diverse mosaic of ecological niches and microhabitats (Diacon-
61 Bolli et al. 2012). They are found on oligo- to mesotrophic soils that are sensitive to eutrophication
62 (Bobbink et al. 1998, Bobbink et al. 2011). Maintaining these grasslands requires low-input agricultural
63 management to prevent accumulation of soil nutrients as well as and to impede reforestation (Poschlod
64 and Wallis De Vries 2002). Semi-natural grasslands also provide numerous ecosystem functions and
65 services. For example, by supporting high abundance and diversity of invertebrates, they may provide
66 pollination and pest control services for surrounding agricultural areas (Byrne and delBarco-Trillo 2019).
67 They can be important for soil and water protection against pollution (Peciña et al. 2019) and may act as
68 hydrological buffers (Gimmi et al. 2011). Semi-natural grasslands were also found to mitigate droughts or
69 floods and reduce carbon dioxide emissions due to their enhanced carbon storage capacities compared to
70 arable land (Peciña et al. 2019). However, semi-natural grasslands are under multiple pressures.

71 Since the late 19th century, semi-natural grasslands have been drastically reduced in their extent and
72 connectivity (Wallis De Vries et al. 2002) as their low productivity made them prone prime for conversion
73 into more profitable high-input agricultural land, or on the contrary, for complete abandonment (Quétier
74 et al. 2007, Török and Dengler 2018). In Switzerland, for example, 99.95% of semi-natural grasslands
75 were lost by during the beginning course of the 20th past century (Gimmi Lachat et al. 2011 2010). As a
76 consequence, efforts to protect the remaining areas were greatly enhanced, but their ongoing loss could
77 not be stopped (Gattlen et al. 2017). Today, these grasslands represent species-rich islands in a landscape
78 dominated by intensive agriculture. It became evident that sustainable conservation has to integrate

79 restoration to actively extend and re-connect these fragmented remnants and to re-enable metapopulation
80 dynamics and genetic exchange of biotic communities among the isolated patches ([GimmiLachat et al.](#)
81 [2014](#)[2010](#)). Hence, converting adjacent intensively managed grasslands into semi-natural grasslands
82 became the focus of restoration projects (Kiehl et al. 2010, Kardol and Wardle 2010). Intensively
83 managed grassland generally represents a highly eutrophic and homogenized habitat, dominated by only a
84 few competitive generalist species while habitat specialists are scarce (De Deyn et al. 2003, Kardol and
85 Wardle 2010). [When restoring](#)[Thus, successful conversion of](#) such [sites, the question is how to overcome](#)
86 [the intensively managed grasslands into nutrient poor and species rich communities relies on overcoming](#)
87 [their agricultural legacy, which is preserved in the overabundant soil, but is also expressed in nutrients as](#)
88 [well as](#) poor species, [or and](#) propagule availability (Bakker and Berendse 1999, [McLauchlan 2006,](#)
89 [Brinkman et al. 2017](#)).

90 Various restoration strategies have been tested over the past decades. They affect above- and
91 belowground, biotic and abiotic properties differently depending on their intervention intensity (e.g.,
92 Marrs et al. 1998, Kiehl and Pfadenhauer 2007, Kardol et al. 2008, Frouz et al. 2009, Suding 2011). Mild
93 interventions, such as cessation of fertilization and multiple plant biomass harvests, have been rarely
94 successful in lowering the high availability of soil nutrients and re-establishing targeted plant
95 communities. Conversely, more severe interventions, such as topsoil removal with and without seed
96 addition, were found to be highly successful in restoring oligotrophic grassland ecosystems (see review in
97 Kiehl et al. 2010). However, removal of the nutrient-rich topsoil, typically a layer of 20 to 50 cm,
98 substantially affects belowground biota and abiotic soil conditions, and is therefore viewed rather
99 critically (see Geissen et al. 2013).

100 Yet, to evaluate restoration success, usually only a few aboveground biotic properties, typically plant
101 community composition, sometimes the presence/absence of selected insect species or taxa (e.g.,
102 grasshoppers, beetles) are used (e.g., Patzelt et al. 2001, Kardol et al. 2005, Kiehl & Wagner 2006, Kiehl
103 & Pfadenhauer 2007, Klimkowska et al. 2007, Verhagen et al. 2008, Neff et al. 2020). More exhaustive
104 evaluations are lacking and only few studies assessed belowground community composition and soil

105 properties to determine restoration success (e.g., Kardol et al. 2009b, Frouz et al. 2009, Wubs et al. 2016,
106 Resch et al. 2019). As restoration methods should enhance and re-establish biodiversity and ecosystem
107 functioning both above- and belowground, success should be evaluated based on a comprehensive
108 assessment of biotic and abiotic, above- and belowground properties, such as taxonomic and structural
109 diversity, and soil functions and processes (Havlicek 2012, Greiner et al. 2018, Gann et al. 2019). Thus, a
110 multifunctional approach could be highly suitable to validate successful re-establishment of the targeted
111 species or ecosystem properties and functions over time (see review in Manning et al. 2018, but also see
112 Meyer et al. 2015, Costantini et al. 2016).

113 In the present study, we assessed how three restoration methods of different intervention intensities,
114 i.e., *Harvest only* (biomass removal), *Topsoil* (topsoil removal), and *Topsoil+Propagules* (topsoil
115 removal plus addition of target plant species), succeeded in restoring ecosystem multifunctionality. We
116 included 13 properties, namely aboveground arthropod richness, belowground faunal and microbial taxon
117 richness, plant species richness, vegetation structure, above- and belowground functional diversity and
118 food-web complexity, soil heterogeneity, soil carbon (C) storage, water holding capacity, nutrient
119 retention capacity and soil net nitrogen (N) mineralization in our ecosystem multifunctionality metric.
120 Restoration success was compared to both intensively managed grasslands (*Initial* state) and ancient
121 semi-natural grasslands (*Target* state). The evaluation took place 22 years after restoration methods were
122 implemented. To our knowledge, this is the first long-term study that combined aboveground and
123 belowground ecosystem multifunctionality to evaluate the recovery of targeted ecosystem properties after
124 grassland restoration. As measuring and assessing various ecosystem properties is cost-intensive, we
125 conducted a “cost-benefit analysis” to determine which and how many ecosystem properties are needed to
126 define ecosystem multifunctionality in restored grasslands as accurateaccurately as possible, but at
127 affordable costs (effort, infrastructure, expert knowledge). This analysis should help environmental
128 agencies that supervise restoration programs in their decision-making process. Overall, we aimed to
129 answer the following research questions:

130 1. Does multifunctionality differ between intensively managed and semi-natural grasslands?

- 131 2. Are the different restoration methods successful in restoring grassland multifunctionality?
- 132 3. How much do biotic and abiotic, above- and belowground properties contribute to ecosystem
- 133 multifunctionality?
- 134 4.—Which ecosystem properties are the best indicators to accurately describe multifunctionality in
- 135 restored grasslands in a cost-effective way?

136

137

For Review Only

138 **MATERIAL AND METHODS**139 **Study area**

140 The study was conducted in the Canton of Zurich, Switzerland, in and around two nature reserves
141 *Eigental* and *Altläufe der Glatt* ($47^{\circ}27'$ to $47^{\circ}29'$ N, $8^{\circ}37'$ to $8^{\circ}32'$ E, 417 to 572 m a.s.l.). **Mean annual**
142 **temperature** All studied grasslands were located with a radius of approximately 4 km. **Average monthly**
143 **temperatures** range from 0.7 ± 2.0 °C (January) to 19.0 ± 1.5 °C (July), and **monthly** precipitation ~~are 9.68~~
144 ~~± 0.56 °C and 992 ± 167~~ range from 60 ± 42 mm, respectively (1987 (January) to 118 ± 46 mm (July
145 **[maxima]**; 1989–2017; MeteoSchweiz 2018). The two nature reserves contain small-scale grassland
146 mosaics differing in their nutrient and water availability. In our study, we focused on semi-dry and semi-
147 wet oligo- to mesotrophic grasslands characterized by high plant species richness and groundwater
148 fluctuations throughout the year (Delarze et al. 2015, see also Resch et al. 2019).

149

150 **Experimental design and sampling**

151 A large-scale restoration experiment to expand and reconnect isolated remnants of species-rich
152 grasslands was initiated in the nature reserve *Eigental* in 1990. Twenty hectares of adjacent intensive
153 grasslands were chosen for restoration. In 1995, three restoration methods of increasing intervention
154 intensities were implemented. The goal of all three methods was to lower the availability of soil nutrients
155 and hence, facilitate ecosystem development towards the targeted nutrient-poor grasslands. These
156 methods were: *Harvest only* (hay harvest twice a year), *Topsoil* (removal of the nutrient-rich topsoil), and
157 *Topsoil+Propagules* (~~Topsoil+topsoil~~) removal combined with the application of hay from target
158 vegetation; further details see Resch et al. 2019). Plant biomass harvest (once a year in late summer/early
159 autumn) commenced in *Topsoil* and *Topsoil+Propagules* five years after the soils were removed. **and is**
160 **still ongoing today (see Appendix 1: Table S1)**. We measured restoration success by comparing the three
161 restoration methods with intensively managed (*Initial*) and semi-natural grasslands (*Target*) 22 years after
162 restoration. *Initial* grassland sites share the same agricultural history as the restored sites: mowing and

163 subsequent fertilizing (manure) up to five times a year, as well as different tillage regimes (see Appendix
164 S1: Table S1; Resch et al. 2019). *Target sites were the sites from which hay for seeding the*
165 *Topsoil+Propagules sites was collected. Soil conditions (i.e., soil types, soil texture) were comparable to*
166 *those found in the restored grasslands (see Appendix S1: Table S1; Resch et al. 2019). Additionally,*
167 *Target sites were selected to represent a variety of semi-natural grasslands, including semi-dry to semi-*
168 *wet conditions.* In *Target* grasslands, biomass is harvested once a year in late summer or early autumn.
169 Eleven 5 m x 5 m (25 m²) plots were randomly established in each of the five treatments (in total 55 plots;
170 for a detailed map see Neff et al. 2020). An additional 2 m x 2 m (4 m²) subplot was randomly established
171 at least 2 m away from each 25 m² plot for destructive sampling (see details below). Data sampling took
172 place between June and September 2017.

173

174 *Vegetation properties*

175 All plant species were identified within the 25 m² plots (nomenclature: Lauber and Wagner 1996) in
176 mid-June 2017 (in total 250 species). Vegetation structure and plant biomass were assessed diagonally on
177 a transect of 2 m x 10 cm within the 25 m² plot in early July 2017. We measured the maximum and mean
178 height of the vegetation at the start, middle and end of the transect and calculated the standard deviation
179 of these measures to describe vegetation structural heterogeneity (Schuldt et al. 2019). Thereafter,
180 biomass was clipped on the entire transect to 1 cm height, sorted into five functional groups (graminoids,
181 forbs, legumes, litter, and woody species; *Data repository: <https://doi.org/10.16904/envidat.169>*), dried at
182 60 °C for 48 h, and weighed (Meyer et al. 2015).

183

184 *Aboveground arthropods*

185 Aboveground arthropods were sampled at two locations in each 25 m² plot in early July 2017 (see also
186 Neff et al. 2020). Briefly, two cylindrical baskets (50 cm diameter, 67 cm height; woven fabric) were
187 thrown simultaneously from outside the plot into two opposite corners. A closable mosquito mesh sleeve
188 was mounted to the top of the baskets and an integrated metal ring at the bottom was fixed to the ground

189 with metal stakes to assure that insects could not escape. A suction sampler (Vortis, Burkhard
190 Manufacturing Co. Ltd., Hertfordshire, England) was then inserted into one of the baskets through the
191 opening of the sleeve and the plot was "vacuumed" twice for 105 seconds with a 30 seconds break. The
192 collected animals were immediately transferred into 70-% ethanol. Arthropods were sorted and assigned
193 to 23 taxonomic groups (Appendix S1: Table S3; [Data repository: https://doi.org/10.16904/envidat.169](https://doi.org/10.16904/envidat.169)).
194 Holometabolic larvae were lumped into one category while hemimetabolic larvae were grouped
195 separately from adults in the respective taxonomic rank. We used mean values of individuals per plot for
196 total abundance. Aboveground arthropod richness was defined by the number of different taxa to lowest
197 taxonomic level (in total 23 taxa). All taxa were assigned to one of five trophic levels: 1) primary
198 producers, 2) primary consumers, 3) secondary consumers, 4) tertiary consumers, and 5) quaternary
199 consumers (Appendix S1: Table S3).

200

201 *Belowground fauna*

202 Sampling of all belowground fauna took place in mid-July 2017. Earthworms were sampled in two 30
203 cm x 30 cm x 20 cm soil monoliths at two opposite corners of the 25 m² plot (opposite to aboveground
204 arthropod sampling). The excavated soil monolith was broken by hand, all earthworms collected and
205 immediately transferred in a 4-% formaldehyde solution. Thereafter, earthworm individuals were
206 identified to species level (in total 10 taxa; Christian and Zicsi 1999) and species assigned to three
207 functional groups (Appendix 1: Table S3; [Data repository: https://doi.org/10.16904/envidat.169](https://doi.org/10.16904/envidat.169); Bouché
208 1977).

209 To assess soil arthropod communities, we randomly collected one undisturbed soil core (5 cm
210 diameter, 12 cm depth) in each 4 m² subplot with a slide hammer corer lined with a plastic sleeve (AMS
211 Samplers, American Falls, Idaho, USA). Soil arthropods were extracted using Berlese-Tullgren funnels (3
212 mm mesh), starting the day of sampling and lasting 14 days. Individuals were stored in 70-% ethanol. Soil
213 arthropods were assigned to 41 taxonomic groups and 4 feeding types (Appendix 1: Table S3); [Data
214 repository: https://doi.org/10.16904/envidat.169](https://doi.org/10.16904/envidat.169)). Holometabolic and hemimetabolic larvae were treated

215 as previously described for aboveground arthropods. Belowground arthropod richness refers to the 41
216 taxonomic groups.

217 For soil nematode sampling, we randomly collected eight soil cores of 2.2 cm diameter (Giddings
218 Machine Company, Windsor, CO, USA) within each 4 m² subplot to a depth of 12 cm. The eight cores
219 were combined, gently homogenized, placed in coolers, kept at 4 °C and transported to the laboratory at
220 NIOO in Wageningen (NL) within one week after collection. Free-living nematodes were extracted from
221 200 g of fresh soil using Oostenbrink elutriator (Oostenbrink 1960) and prepared for morphological
222 identification and quantification as described by Resch et al. (2019). Nematodes were identified to family
223 level (39 taxa) according to Bongers (1988), assigned to 17 functional groups, 5 feeding types and 5
224 colonizer-persister (C-P) classes (Appendix 1: Table S3; Data repository:
225 <https://doi.org/10.16904/envidat.169>; Yeates et al. 1993, Bongers 1990, Resch et al. 2019).

226 We randomly collected two more soil cores (2.2 cm diameter x 12 cm depth) within each 4 m² subplot
227 to determine soil microbial communities. Again, the soil cores were combined, homogenized, placed in
228 coolers and transported to the laboratory at WSL in Birmensdorf (Switzerland) where the metagenomic
229 DNA was extracted from 8 g sieved soil (2 mm) using the DNeasy PowerMax Soil Kit (Qiagen, Hilden,
230 NRW, GER) according to the manufacturer's instructions. PCR amplification of the V3-V4 region of the
231 prokaryotic small-subunit (16S) and the ribosomal internal transcribed spacer region (ITS2) of eukaryotes
232 was performed with 1 ng of template DNA utilizing PCR primers and conditions as previously described
233 (Frey et al., 2016). PCRs were run in triplicates and pooled. The pooled amplicons were sent to the
234 Genome Quebec Innovation Centre (Montreal, QC, Canada) for barcoding using the Fluidigm Access
235 Array technology (Fluidigm) and paired-end sequencing on the Illumina MiSeq v3 platform (Illumina
236 Inc., San Diego, CA, USA). Quality filtering, clustering into operational taxonomic units (OTUs) and
237 taxonomic assignment were performed as described by Frey et al. (2016) and Adamczyk et al. (2019). We
238 used a customised pipeline largely based on UPARSE (Edgar 2013) implemented in USEARCH v. 9.2
239 (Edgar 2010). After discarding singletons of dereplicated sequences, clustering into OTUs with 97%
240 sequence similarity was performed (Edgar 2013). Quality-filtered reads were mapped on the filtered set of

241 centroid sequences. Taxonomic classification of prokaryotic and fungal sequences was conducted
242 querying against most recent versions of SILVA (v.132, Quast et al. 2013) and UNITE (v.8, Nilsson et al.
243 2018). Only taxonomic assignments with confidence rankings equal or higher than 0.8 were accepted
244 (assignments below 0.8 set to unclassified). Prokaryotic OTUs assigned to mitochondria or chloroplasts
245 as well as eukaryotic OTUs assigned other than fungi were removed prior to data analysis. In addition,
246 prokaryotic and fungal datasets were filtered to discard singletons and doubletons. Thereafter, OTU
247 abundance matrices were rarefied to the lowest number of sequences per community, to normalize the
248 total number of reads and achieve parity between samples (Prokaryota: 29,843 reads; Fungi: 26,690
249 reads). Finally, prokaryotic and fungal observed richness (number of OTUs) were estimated (Prokaryota:
250 14,010 OTUs; Fungi: 5,813 OTUs). For prokaryotes, we distinguished five and for fungi six functional
251 types [based on lowest taxonomic resolution](#) (Appendix 1: Table S3; [Data repository](#):
252 <https://doi.org/10.16904/envidat.169>; Nguyen et al. 2016, Tedersoo et al. 2014). Belowground taxon
253 richness was defined by the total number of earthworm, arthropod, nematode, fungi, and prokaryote taxa
254 assigned to lowest taxonomic level. Finally, all belowground taxa were assigned to the same five trophic
255 levels as the aboveground arthropods (Appendix 1: Table S3; [Data repository](#):
256 <https://doi.org/10.16904/envidat.169>).

257

258 *Soil chemical and physical properties, soil nitrogen mineralization*

259 We randomly collected three 5 cm diameter x 12 cm depth soil samples in each 4 m² subplot with a
260 slide hammer corer (AMS Samplers, American Falls, Idaho, USA), pooled them and then made two
261 subsamples. One was field-fresh and stored at 3 °C until analysis, the other was dried for 48 h at 60 °C
262 and passed through a 4 mm mesh. From the dried sample, we measured soil pH potentiometrically in 0.01
263 M CaCl₂ (soil:solution ratio=1:2, 30 minutes equilibration time). Total and organic carbon content were
264 measured on fine-ground samples (≤ 0.5 mm) by dry combustion using a CN [analyseranalyzer](#) NC 2500
265 (CE Instruments, Wigan, United Kingdom). Inorganic carbon of samples with a pH > 6.5 was removed
266 with acid [vapourvapor](#) prior to analysis of organic carbon (Walther et al. 2010). We calculated total soil

267 carbon (C) storage after correcting its content for soil depth, stone content and density of fine earth (see
268 below). Exchangeable cations were determined on another 5 g dry soil sample with 50 mL unbuffered 1
269 M NH₄Cl solution (soil:solution ratio=1:10, end-over-end shaker for 1.5 hours) and measured by an ICP-
270 OES (Optima 7300 DV, Perkin-Elmer, Waltham, Massachusetts, USA). Thereafter, cation exchange
271 capacity (CEC) was calculated as the sum of exchangeable cations and protons (and expressed as mmol_c
272 per 1 kg soil) and used to describe nutrient retention capacity in our plots. Concentrations of
273 exchangeable protons were calculated as the difference between total and Al-induced exchangeable
274 acidity as determined by the KCl-method (Thomas 1982).

275 Ammonium (NH₄⁺) and nitrate (NO₃⁻) were extracted from a 20 g fresh subsample with 80 mL 1M
276 KCl for 1.5 hours on an end-over-end shaker and filtered through ashless folded filter paper (DF 5895
277 150, ALBET LabScience, Hahnemühle FineArt GmbH, Dassel, Germany). NH₄⁺ concentrations were
278 determined colorimetrically by automated flow injection analysis (FIAS 300, Perkin-Elmer, Waltham,
279 Massachusetts, USA). NO₃⁻ concentrations were measured colorimetrically according to Norman and
280 Stucki (1981). ~~Soil~~Potential soil net nitrogen (N) mineralization was assessed during an 8-week
281 incubation period under controlled moisture (60-% of field capacity, see below), temperature (20 °C) and
282 light conditions (dark) in the laboratory. We weighed duplicate samples of fresh soil equivalent to 8 g dry
283 soil (24 h at 104 °C) into 50 mL Falcon tubes. Soil samples were extracted for NH₄⁺ and NO₃⁻ at the
284 beginning and after eight weeks as described above. Soil net N mineralization was calculated as the
285 difference between the inorganic nitrogen (NH₄⁺ and NO₃⁻) before and after the incubation (Hart et al.
286 1994), corrected for the total incubation time and represented per day values expressed as mg N kg⁻¹ soil
287 d⁻¹.

288 To assess soil physical properties, we randomly collected one undisturbed soil core per 4 m² subplot (5
289 cm diameter, 12 cm depth) in a steel cylinder that fit into the slide hammer (AMS Samplers, American
290 Falls, Idaho, USA). The cylinder was capped in the field to avoid disturbance. We then measured field
291 capacity in the laboratory. For this purpose, the cylinder and soil therein were saturated in a water bath
292 and drained on a sand/silt-bed with a suction corresponding to 60 cm hydrostatic head. The moist soil was

293 dried at 105 °C to constant weight. Field capacity was calculated by dividing the mass of water by the
294 total mass of wet soil contained at 60 cm hydrostatic head and used to describe water holding capacity.
295 Thereafter, samples were passed through a 4 mm mesh. Fine-earth and skeleton fractions were weighed
296 separately to assess bulk soil density (fine-earth plus skeleton), density of fine earth, and proportion of
297 skeleton. Particle density was determined with the pycnometer method (Blake and Hartge 1986), and total
298 porosity and proportion of fine pores were calculated (Danielson and Sutherland 1986). Clay, silt, and
299 sand contents were quantified with the sediment method (Gee and Bauder 1986).

300 Surface and soil temperature (12 cm depth, water-resistant digital pocket thermometer; IP65, H-B
301 Instrument, Trappe, Pennsylvania, USA) as well as volumetric soil moisture content (12 cm depth, time
302 domain reflectometry; Field-Scout TDR 300, Spectrum Technologies, Aurora, Illinois, USA) were
303 measured at five random locations within the 4 m² subplots every month from June to September. We
304 calculated the standard deviation of each temperature and moisture measure over four months to describe
305 seasonal variations. Slope inclination was determined at plot-level via GPS measurements (GPS 1200,
306 Leica Geosystem, Heerbrugg, Switzerland) and categorized into slope gradient classes according to FAO
307 standards (1990). Thickness of the topsoil horizon (equivalent to Ah or Aa horizon) was determined at
308 one soil monolith (30 x 30 x 30 cm³) per 4 m² subplot in cm and rounded to next integer.

309

310 **Ecosystem properties and multifunctionality (Research question 1 - 3)**

311 In total, we used 13 ecosystem properties that represented four major ecosystem attributes, namely
312 biodiversity (plant species richness, aboveground arthropod richness, belowground taxon richness),
313 structural diversity (vegetation structure, soil heterogeneity, above- and belowground functional diversity,
314 above- and belowground food-web complexity), soil functions (soil C storage, water holding capacity,
315 nutrient retention capacity), and soil processes (soil net N mineralization, Appendix S1: Table S2).

316 Selection of the 13 properties was based on suggested international principles and standards on
317 ecological restoration of the Society for Ecological Restoration (SER), and thus, included standardized
318 indicators of restoration success (McDonald et al. 2016, Gann et al. 2019). We used individual properties

319 that were shown to increase ecosystem functioning and invasion resistance, i.e. ecosystem stability, two
320 major goals in ecological restoration (details on rationales see Appendix S1: Table S2). Thus, we assumed
321 that restoring these properties and increasing their values is mandatory to meet the primary objective of a
322 restoration project, namely restoring high levels of ecosystem functioning and strengthening of ecosystem
323 stability (Gann et al. 2019).

324 Soil heterogeneity was calculated based on 20 soil properties (soil pH, organic C content, NO_3^- and
325 NH_4^+ concentrations, concentrations of exchangeable cations [Ca, K, Mg, Na, Mn], bulk density, texture,
326 proportion of skeleton and fine pores, thickness of topsoil horizon, slope class, seasonal variation in
327 surface and soil temperature as well as ~~and~~-soil moisture). We z-transformed the 20 properties and then
328 calculated multivariate Euclidean distances for all pairwise between- and within-group combinations for
329 each treatment. We then used differences in group homogeneities based on group dispersion variances,
330 i.e., distance of single plot to its corresponding group centroid to obtain soil heterogeneity (betadisper
331 function of the vegan package, Oksanen et al. 2019, Alsterberg et al. 2017).

332 We calculated functional diversity for plants using shoot biomass of plant functional groups and for
333 faunal and microbial communities by assigning all taxonomic levels to functional groups. In total, 46
334 functional groups were defined based on lowest taxonomic resolution for each biotic community (see
335 Appendix S1: Table S3; Data repository: <https://doi.org/10.16904/envidat.169>). We calculated
336 multivariate Euclidean distances on z-transformed functional groups (relative abundances) for all pairwise
337 combinations of treatments and defined functional diversity above- and belowground using differences in
338 group homogeneities based on group dispersion variances.

339 Food-web complexity for faunal and microbial functional groups was based on life-history traits. For
340 each functional group we assigned: 1) feeding type, 2) trophic level, and 3) sensitivity to stress and/or
341 disturbance and recolonization ability (SD level), based on well-established bioindicative methods
342 (Bongers 1990, Parisi et al. 2005). For this study, we extended these methods to also address aboveground
343 arthropods, earthworms, prokaryotes and fungi. The ecomorphological index concept of soil
344 microarthropods (Parisi et al. 2005) was adopted for aboveground arthropods. For earthworms, we ranked

345 the sensitivity according to the r- and K-strategy (Römbke et al. 2005): sensitivity was ranked lowest for
346 epigeic species (one), followed by endogeic (five) and highest for anecic species (nine). The prokaryotic
347 community was classified based on copiotrophic-oligotrophic characteristic (for a review see Ho et al.
348 2017): copiotrophic and undefined bacteria received lowest (one), oligotrophic bacteria highest (nine)
349 rank. The fungal community was ranked based on the copiotrophic-oligotrophic concept only if known
350 (for a review also see Ho et al. 2017): copiotrophic saprotrophs, pathotrophs (excluding animal) and
351 undefined fungi were ranked lowest (one); symbiotrophs, biotrophs, animal pathogens and oligotrophic
352 saprotrophs received highest ranking (nine); saprotrophs (excluding oligo- or copiotrophs) and others
353 received an intermediate ranking (five). We then defined the trait-based factor as follows: 1) the digit
354 before the comma was defined by the feeding type and trophic level (ranging from one to five), 2) the
355 digit after the comma corresponded to stress/disturbance sensitivity and recolonization ability (ranging
356 from 1 to 9). Higher values of the trait-based factor indicated higher food-web complexity (see Appendix
357 S1: Table S3). We calculated weighted abundance per functional group by multiplying relative abundance
358 per functional group with its corresponding trait-based factor. Thereafter, food-web complexity was
359 defined as the standardized community weighted mean for the above- and belowground communities
360 separately.

361 We calculated five different multifunctionality measures using the averaging approach (Hooper and
362 Vitousek 1998). Ecosystem multifunctionality included all 13 ecosystem properties. We also calculated
363 aboveground multifunctionality (plant richness and vegetation structure, aboveground arthropod richness,
364 functional diversity, food-web complexity), belowground multifunctionality (belowground taxon
365 richness, functional diversity, food-web complexity, soil heterogeneity, soil C storage, water holding
366 capacity, nutrient retention capacity, soil net N mineralization), biotic multifunctionality (aboveground
367 arthropod richness, belowground taxon richness, plant richness, vegetation structure, above- and
368 belowground functional diversity, food-web complexity), and abiotic multifunctionality (soil
369 heterogeneity, soil C storage, water holding capacity, nutrient retention capacity and soil net N
370 mineralization). We did not use the threshold approach (Gamfeldt et al. 2008) as we were not interested in

371 assessing the number of properties performing above a certain threshold, but comparing levels of
372 multifunctionality in restored systems with those of our targeted semi-natural grasslands. The availability
373 of a real-world target rather than any arbitrarily chosen threshold justifies the use of the averaging
374 approach (Byrnes et al. 2014, Gamfeldt and Roger 2017).

375 All five multifunctionality measures were calculated after standardizing each ecosystem property
376 (Delgado-Baquerizo et al. 2019). For belowground taxon richness, functional diversity and food-web
377 complexity, standardization was applied within each faunal and microbial group before averaging to
378 counteract overrepresentation of microbial taxa. All ecosystem properties were weighted equally for
379 multifunctionality calculations. Potential collinearity between all pairs of individual ecosystem properties
380 was assessed using Pearson correlations to ensure that no highly correlated variables ($r > |0.7|$) were
381 included, and specifically, that no opposing performance (i.e., strong negative correlations) among the
382 individual ecosystem properties was present (Dormann et al. 2013; Appendix S1: Fig. S1).

383 Treatment differences (explanatory variable) in multifunctionality measures and the 13 ecosystem
384 properties (dependent variables) were assessed using beta regression on standardized values (Ferrari and
385 Cribari-Neto 2004). As beta regression models do only allow for values between 0 and 1 but not both
386 extremes (relevant only for individual properties), we transformed our data accordingly (Smithson and
387 Verkuilen 2006). Significant differences between treatments were identified using likelihood ratio tests
388 (lrtest function of the lmtest R package, Zeileis and Hothorn 2002). Post-hoc pairwise comparisons were
389 adjusted for multiple testing using the Bonferroni correction-method in combination with the false
390 discovery rate approach (cld function of the multcomp R package, Hothorn et al. 2008).

391

392 **Most cost-effective ways to describe multifunctionality (Research question 4)**

393 We assessed which ecosystem property or which combination of ecosystem properties explained the
394 highest amount of ecosystem multifunctionality at the lowest possible costs. For this purpose we
395 calculated 8190 alternative models using linear regression as implemented in an exhaustive search
396 approach (regsubsets function of the leaps R package, Lumley 2020). These models contained all possible

397 combinations of 13 ecosystem properties, hence we obtained a series of models that included 12
398 properties (all in EMF.12), a series of models that included 11 properties (EMF.11) and so forth
399 (Appendix S2). In a first step, we compared how much variation of ecosystem multifunctionality each of
400 these alternative models explained, using the Bayesian information criterion ($\Delta\text{BIC} > 2$, Table 1,
401 Kassambra 2018). We then selected the best models with 12, 11, 10, etc. variables.

402 We estimated costs to each ecosystem property by approximating costs for effort, infrastructure and
403 expert knowledge that are necessary to collect each of our 13 ecosystem properties (Appendix S1: Table
404 S4-S7). Costs were classified into coarse categories, represented by pluses (+) and where higher costs
405 equated to more +. We then assigned these costs to each alternative model described above by summing
406 the costs of all ecosystem properties included in the respective models (Appendix S2). We selected the
407 models with 12, 11, 10, etc. variables with the lowest costs (Table 2). Thus, we were able to evaluate how
408 much an alternative model explained and how much it would roughly cost to collect the data contained in
409 it.

410 All statistical analyses and graphical outputs were performed in R version 3.6.0 (R Core Team 2019).

411 A full list of all packages and functions used can be found in Appendix S1: Table S5.

412

413 S8.

414 RESULTS

415 Ecosystem multifunctionality was higher in all three restored treatments than in *Initial*, but only
416 *Topsoil* and *Topsoil+Propagules* reached *Target* levels (Fig. 1A). Treatment differences in ecosystem
417 multifunctionality were mainly associated to differences in aboveground (Fig. 1B) and biotic (Fig. 1D)
418 multifunctionality, with the two topsoil removal treatments reaching higher levels than *Harvest only*.
419 Interestingly, the two topsoil removal treatments resulted in even higher aboveground and biotic
420 multifunctionality than *Target* (Fig. 1B, 1D). Belowground (Fig. 1C) as well as abiotic (Fig. 1E)
421 multifunctionality did not differ among the three restoration methods, but were significantly higher than
422 in *Initial* and significantly lower than in *Target* (exception: belowground multifunctionality in *Topsoil*).
423 Aboveground, belowground, biotic and abiotic multifunctionality were positively correlated with
424 ecosystem multifunctionality (Appendix S1: Figs. S2A-D).

425 Six out of the 13 ecosystem properties contributed significantly to both explaining ecosystem
426 multifunctionality and discriminating among the five treatments: Plant species richness, vegetation
427 structure, belowground functional diversity, aboveground food-web complexity, soil C storage, and soil
428 net N mineralization (Fig. 2, Table 1, Appendix S1: Fig. S3).

429 Including more variables into our model explained more variation in ecosystem multifunctionality.
430 Yet, naturally, this also increases the costs of collecting the data. The model including all 13 ecosystem
431 properties equals 100-% ecosystem multifunctionality and would cost the most (77+). Interestingly, we
432 found negative relationships between explained variation in ecosystem multifunctionality and costs for
433 each group of models that included the same number of variables (Fig. 23). This means, low-cost
434 measures explained relatively more variation of ecosystem multifunctionality compared to high-cost
435 measures within a model cluster (Fig. 23, Table 1 and 2). Models with two or more properties included
436 were able to explain $\geq 70\%$ of ecosystem multifunctionality, however, the costs were 10+ and up (Table
437 2). The “cheapest” model was based on vegetation structure (1+), but explained only 47.7-% of ecosystem
438 multifunctionality (Table 1). Plant species richness accounted for 52.9-% of ecosystem multifunctionality

439 at roughly 4 % (3+) of the cost of the model including all 13 properties (77+) and represented the best
440 individual indicator of all 13 ecosystem properties (Table 1). Plant species richness, in addition,
441 discriminated significantly among the treatments (Fig. 2, Table 1, Appendix S1; Fig. S3).

442 Vegetation structure, soil C storage and water holding capacity together explained 70% of ecosystem
443 multifunctionality at the costs of roughly 8% (6+) of what it took to obtain all 13 variables. On the
444 contrary, by using vegetation structure, soil C storage and water holding capacity we increased the costs
445 by roughly 17% compared to when we only used vegetation structure alone, but we gained 22.3% of
446 explained variation of ecosystem multifunctionality (Table 1). Hence, this model can be considered the
447 most cost-effective while describing a high amount of ecosystem multifunctionality (Table 2).

448 **DISKUSSION**

449 **DISCUSSION**

450 **Restoring grassland multifunctionality**

451 Ecosystem multifunctionality was significantly higher in semi-natural grasslands compared to
452 intensively managed grasslands (research question 1). This is in line with studies showing that intensive
453 agriculture decreases multifunctionality by homogenizing plant and faunal communities and soil
454 properties (e.g., Birkhofer et al. 2012, Gossner et al. 2016, Soliveres et al. 2016), and reducing functional
455 diversity at local and landscape scales (Allan et al. 2015, Neff et al. 2019). In contrast, traditionally
456 managed semi-natural grasslands are characterized by high taxonomic and structural heterogeneity above-
457 and belowground ([GimmiLachat et al. 2014](#), Diacon-Bolli et al. 2012, Byrne and delBarco-Trillo
458 2019, Peciña et al. 2019), thereby supporting multiple functions and services simultaneously.

459 For all three restoration methods we found higher ecosystem multifunctionality than in intensively
460 managed grasslands, but only the two topsoil removal treatments reached *Target* levels within 22 years
461 (research question 2). Thus, these restoration methods allow rebuilding multifunctionality comparable to
462 the targeted semi-natural grasslands over [longerdecadal](#) time frames, which has already been reported
463 from peatlands (Strobl et al. 2019). We also provide strong evidence that topsoil removal not only
464 promoted the restoration of grassland multifunctionality, but also successfully re-established ecosystem
465 multifunctionality comparable to the targeted semi-natural grasslands. Similar results have been reported
466 for Mediterranean forests, where the long-term recovery of forest multifunctionality depended on the
467 intervention intensity of the restoration methods used (natural regeneration vs. active planting, Cruz-
468 Alonso et al. 2019).

469 We assessed 13 different biotic and abiotic, above- and belowground ecosystem properties that
470 represented key attributes of the targeted ecosystem. We specifically focused on integrating belowground
471 ecosystem properties and functions as their recovery during restoration has been suggested essential for
472 evaluation (see Bardgett et al. 2005, Meyer et al. 2015), especially for restoration methods that strongly

473 affect the soil, such as topsoil removal. This comprehensive assessment allowed us to also identify the
474 contribution of the different ecosystem components to multifunctionality of restored grasslands (research
475 question 3). Thereby, we demonstrated that topsoil removal clearly accelerated the recovery of biotic and
476 aboveground multifunctionality while it had no negative long-term effects on abiotic or belowground
477 multifunctionality compared to low intervention methods. Topsoil removal even led to a higher biotic
478 multifunctionality compared to the *targetTarget*, indicating that our measures succeeded in
479 ~~recreating~~ creating species-rich and functional systems. *Nevertheless, which are, however, slightly*
480 *different from our Target sites. Furthermore*, our results also revealed that abiotic multifunctionality in all
481 three restoration methods did not reach target levels, even 22 years after treatment implementation. Thus,
482 the long-term recovery of abiotic soil properties lags behind aboveground properties. This is in line with
483 short-term studies reporting time lags in the response of biotic aboveground and belowground
484 communities to changed soil conditions (see Bardgett et al. 2005, Kardol et al. 2005, 2009a). The
485 apparent failure in recreating soils with an equivalent level of abiotic multifunctionality compared to
486 target systems, therefore, underlines that protection and conservation efforts are most urgently needed to
487 minimize degradation and loss of biodiversity and ecosystem functioning (e.g., United Nations 2015:
488 Sustainable Development Goal 15, Pe'er et al. 2020).

489 Although particular standards for ecological restoration urged the need for comprehensive assessments
490 (see Gann et al. 2019), long-term multifunctionality studies in grassland ecosystems have so far been
491 lacking. In addition, studies assessing the long-term recovery of multiple biotic and abiotic belowground
492 properties after topsoil removal are scarce and primarily focused on individual properties (e.g., Frouz et
493 al. 2009, Wubs et al. 2016, Resch et al. 2019). Here we show that long-term studies that incorporate
494 multiple above- and belowground ecosystem components are important as the evaluation of restoration
495 success strongly depends on the number and identity of the indicators used (e.g., Montoya et al. 2012,
496 Wortley et al. 2013). Thus, we strongly recommend to integrate biotic and abiotic, above- and
497 belowground properties in long-term monitoring programs to appropriately represent the entire
498 ecosystem.

499

500 **Revealing ecosystem multifunctionality in a most cost-efficient way**

501 We used 13 ecosystem properties to calculate ecosystem multifunctionality, which was highly
502 resource-intensive. Monitoring the success of restoration projects is normally resource-limited, only
503 allowing for the collection of a restricted set of properties (Montoya et al. 2012, Gann et al. 2019). To
504 explore which of our 13 properties (alone or in combination) would be best suited to describe ecosystem
505 multifunctionality with relative high accuracy, but at low costs, we conducted a “cost-benefit analysis”
506 (research question 4). Plant species richness was found to be the most accurate individual indicator
507 successfully describing ecosystem multifunctionality (52.9 %), which supports its supremacy as the most
508 commonly used biotic indicator for conservation agencies conducting such restoration monitoring (Kiehl
509 et al. 2010). Vegetation structure would be the cheapest individual property, but still described quite a
510 high amount of ecosystem multifunctionality (47.7 %), hence, could be used instead of plant species
511 richness if funding is limited or experts are scarce, but long-term restoration monitoring is stipulated by
512 statutory regulations. However, vegetation structure complemented with two low-cost belowground
513 properties, i.e. soil C storage and water holding capacity, would allow for a highly cost-effective
514 monitoring of ecosystem multifunctionality. Such a combination provides land managers or nature
515 protection agencies with an accurate measure to monitor how ecosystem multifunctionality is restored
516 over ~~longerdecadal~~ time frames.

517

518 CONCLUSIONS

519 Long-term monitoring of restoration projects is indispensable to implement adaptive management
520 strategies if necessary and assess restoration success. This is of major importance for industries (e.g.,
521 mining companies), governments, communities and land managers ultimately responsible for
522 implementing enforced statutory regulations and the subsequent evaluation of restoration activities in the
523 long-term. Practical standards to monitor and evaluate restoration have already been proposed.
524 Nevertheless, long-term studies combining aboveground and belowground ecosystem multifunctionality
525 assessments to evaluate the recovery of targeted ecosystem properties were lacking. Therefore, the
526 findings of our study can serve as a guideline to monitor and evaluate long-term grassland restoration,
527 using a comprehensive, multifunctional approach.

528 In the advent of the United Nations Decade on Ecosystem Restoration (2021-2030) multiple priorities
529 need to be set to foster the cumulative gains of restoration actions across the globe. Hence, new
530 restoration initiatives should not only focus on defining which specific types of ecosystems or global
531 regions should be prioritized for restoration activities, but also on promoting and implementing cost-
532 efficient properties to accurately assess entire ecosystems and their recovery following restoration. In this
533 study, we showed that for our grassland systems assessing vegetation structure, soil C storage and water
534 holding capacity allows for a highly cost-effective long-term monitoring of ecosystem multifunctionality.
535 As this is one of the first studies considering a multifunctionality approach, further evidence from other
536 ecosystems is needed to validate the generality of our results. Nevertheless, we are highly confident that
537 our findings can serve as a baseline to help overcome funding limitations within restoration projects, often
538 prevalent in less developed countries where restoration activities are especially needed.

539

540 ACKNOWLEDGEMENTS

541 We thank Matthias Diener, Njoku Nwawudu, Anja Marty and Martin Gossner for help in sampling
542 and sorting of invertebrates as well as laboratory work on soil properties; Benjamin Fitzpatrick for
543 suggestions regarding statistical methods; the Genetic Diversity Centre (GDC) of ETH Zurich for
544 suggestions regarding analyzing molecular data; and Roel Wagenaar, Roger Köchli, Daniel Christen,
545 Marco Walser, and Beat Stierli for technical assistance. We also thank the Nature Conservation Agency
546 of Canton Zurich, under the supervision of Pascale Weber and Ursina Wiedmer, for administrative
547 support with farmers, regional commissioners for nature conservation and access permits for the
548 respective nature reserves. This work was supported by the Swiss National Science Foundation (grant
549 number 31003A_166654).

550

551 AUTHORS' CONTRIBUTIONS

552 MCR, ACR, MS, BF, SZ, and NB designed the experiment; MCR, ACR and MS developed the ideas
553 for the manuscript; MCR, SZ and UG collected the data; WHvdP, BF and SZ led the lab work; MCR
554 analyzed the data and wrote the first draft of the paper; ACR and MS commented on all drafts of the
555 paper; NB, BF, UG, SZ and WHvdP contributed critically to the advanced drafts of the paper; all authors
556 gave final approval for publication.

557

558 DATA ACCESSIBILITY

559 Data will be made available via the EnviDat Repository-<https://doi.org/10.16904/envidat.169>. Raw
560 sequences of the soil microbial community will bear deposited in the NCBI Sequence Read Archive
561 under the BioProject accession number PRJNA630536.

844 **TABLES**

845 **Table 1.** Statistical analyses for all 13 ecosystem properties that we used to calculate ecosystem
 846 multifunctionality, and to discriminate among our restored, intensively managed and semi-natural
 847 grasslands (overall, pairwise comparison). Model comparison was based on the explained variation of
 848 ecosystem multifunctionality (r^2) and on the Bayesian information criterion (BIC). Ecosystem properties
 849 are sorted by ecosystem attribute and consecutively numbered (No.). Cost = cost categorization according
 850 to effort, infrastructure and expert knowledge needed for assessment (see Appendix S1: Table S4); r^2 =
 851 Pseudo r^2 ; χ^2 = Chi squared value; ΔBIC = difference in BIC units to the lowest ranked property (lowest
 852 BIC = plant species richness); I = *Initial*; H = *Harvest only*; Ts = *Topsoil*; TsP = *Topsoil+Propagules*; T =
 853 *Target*; AG = aboveground; BG = belowground. Different lower case letters indicate significant differences
 854 between treatments.

855

856

857 **Table 2.** Comparison of top alternative models based on highest explained variation of ecosystem
 858 multifunctionality (EMF) or lowest cost. Alternative ecosystem multifunctionality models were clustered
 859 according to the number of ecosystem properties included in the calculations (EMF.1-12). Alternative
 860 models for highest explanatory power were compared based on the Bayesian information criteria (BIC)
 861 and considered different when the difference in ΔBIC was > 2 (Kassambra 2018; Appendix S2). This was
 862 done for each cluster separately. % EMF = proportion of ecosystem multifunctionality explained; Cost =
 863 total costs for a specific model (Table 1; Appendix S1: Table S4; Appendix S2); Properties considered =
 864 List of ecosystem properties included, numbers correspond to Table 1 (No.).

EMF model	highest explanatory power			lowest cost

866

867 FIGURE LEGENDS

868 **Fig. 1.** Treatment effects on ecosystem (A), aboveground (B), belowground (C), biotic (D) and abiotic
869 (E) multifunctionality (mean \pm SE). All five multifunctionality measures represent weighted average values
870 of standardized properties (y-axis: scaled between 0 and 1). Different lower-case letters indicate significant
871 differences between treatments. I = *Initial*; H = *Harvest only*; Ts = *Topsoil*; TsP = *Topsoil+Propagules*; T
872 = *Target*.

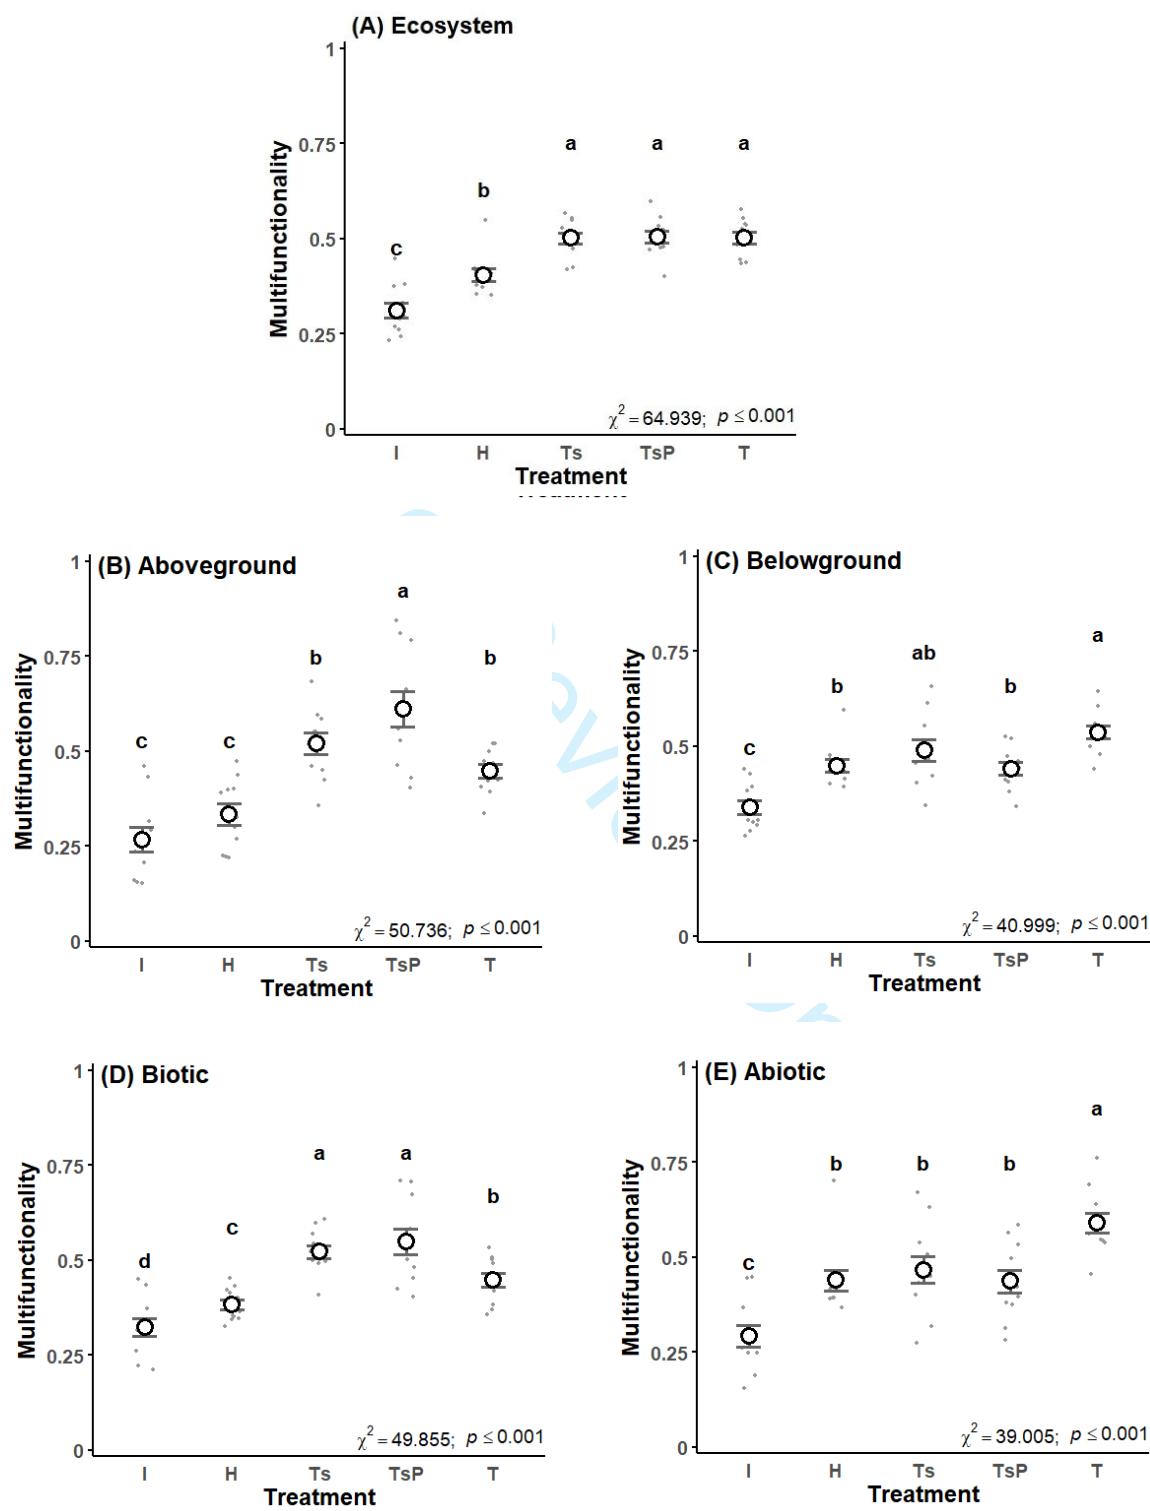

873

874 **Fig. 2.** Treatment effects on standardized ecosystem properties (mean \pm SE; 1-13). Different lower case
875 letters indicate significant differences between treatments. AG = aboveground; BG = belowground; I =
876 Initial; H = Harvest only; Ts = Topsoil; TsP = Topsoil+Propagules; T = Target. Label numbers refer to
877 Table 1 (No.).

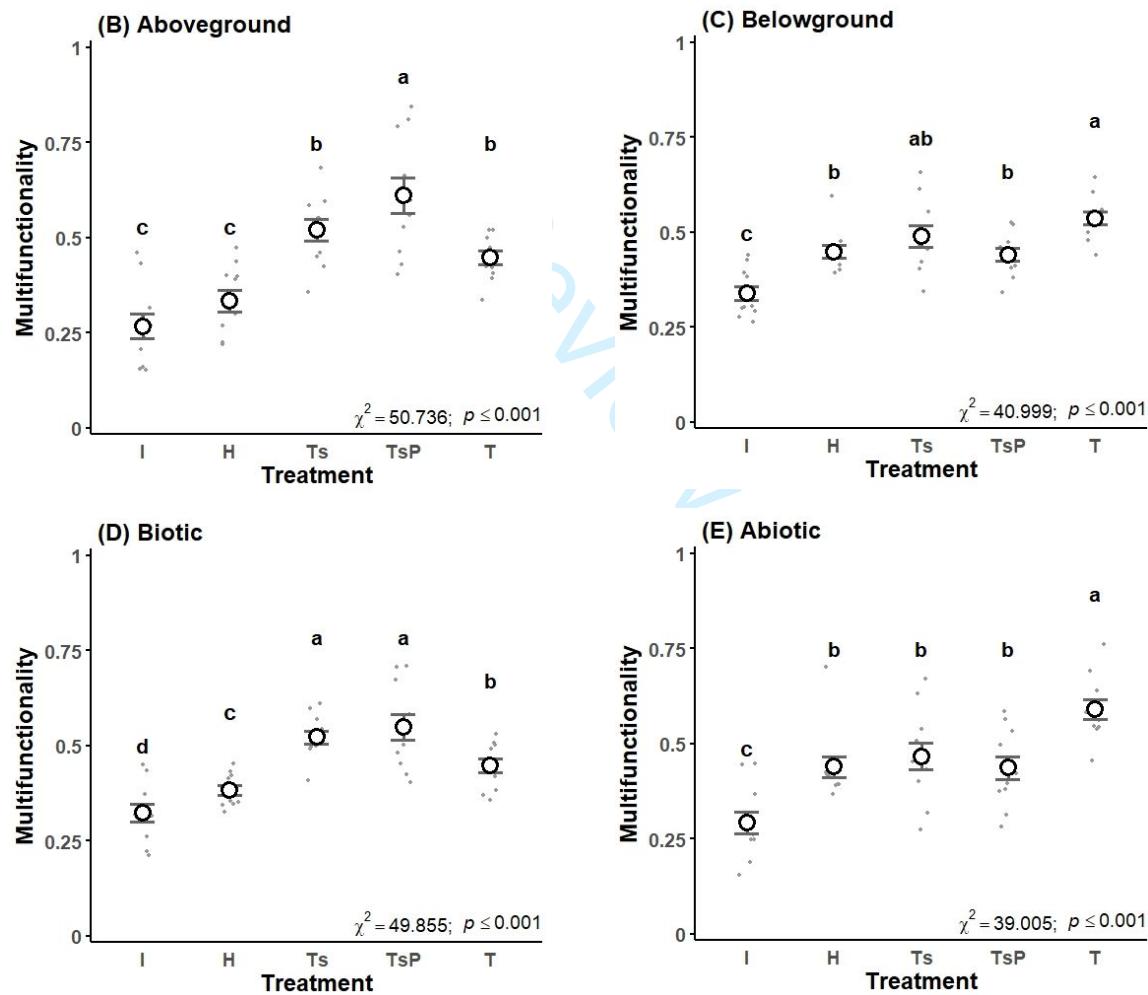

878

879 **Fig. 3.** Relationship of explained variation of ecosystem multifunctionality (EMF) with costs for
880 individual and multiple ecosystem properties. Subsets of possible combinations were identified by the
881 stepwise reduction of all 13 ecosystem properties using an exhaustive search approach, which resulted in
882 8190 alternative calculations of ecosystem multifunctionality (single points; Appendix S2). Alternative
883 calculations of ecosystem multifunctionality were clustered by number of included ecosystem properties
884 (No. variables) and indicated by different colours. Linear regressions were calculated per cluster and
885 also indicated in the respective colours. For comparison, ecosystem multifunctionality calculated
886 based on all 13 properties and the respective costs are also shown (* = Full model).

- 5 **APPENDIX S1.** Supporting information

For Review Only

17 **Figure S1:** Scatterplot matrix for pair-wise comparison of the 13 ecosystem properties using Pearson
 18 correlations. Strength of correlation is size-coded (increasing font size=higher correlation). No highly
 19 correlated variables, i.e. Pearson $> |0.7|$, were identified, therefore all ecosystem properties were kept
 20 for further multifunctionality calculations (Dormann et al. 2013). Ri = richness; AG = aboveground;
 21 BG = belowground; Veg.str = vegetation structure; Soil.het = soil heterogeneity; FD = functional
 22 diversity; FW = food-web complexity; C.stor = soil carbon storage; H2O.cap = water holding
 23 capacity; Nut.ret = nutrient retention capacity; N.min = soil net nitrogen mineralization.

24

25

26 **Figure S2:** Relationship between ecosystem multifunctionality and aboveground (A), belowground
27 (B), biotic (C), and abiotic (D) multifunctionality across all five treatments. Degrees of freedom:
28 numerator=1, denominator=53.

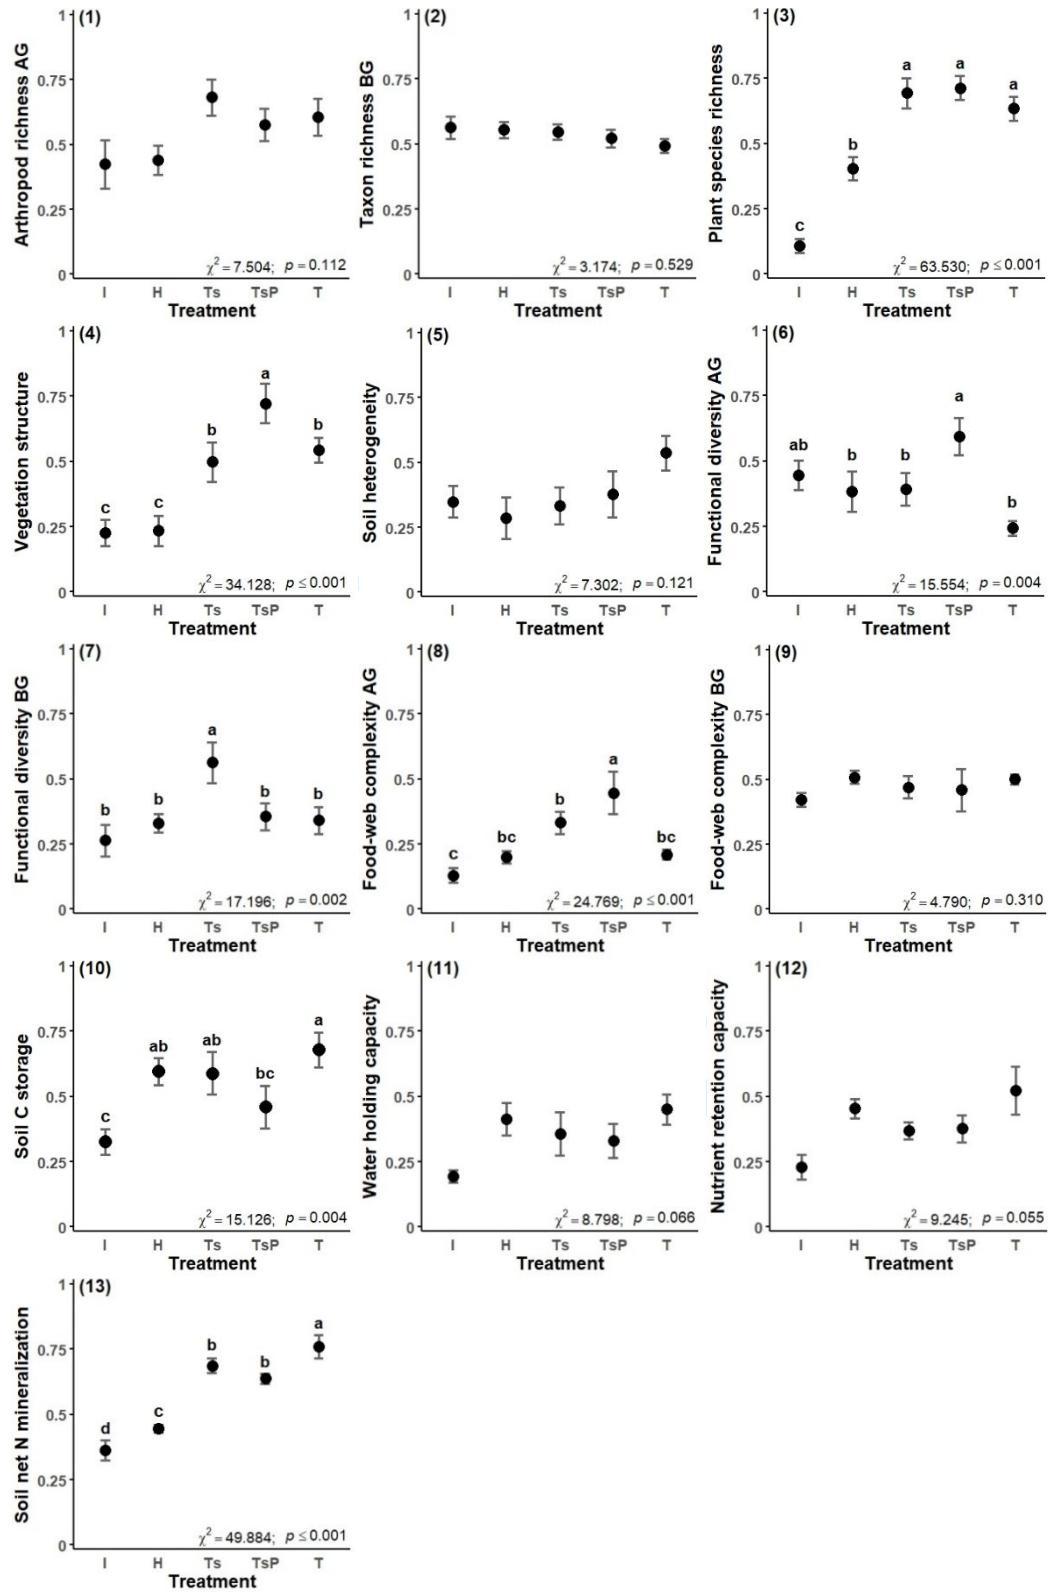

Figure S3: Treatment effects on standardized ecosystem properties (mean \pm SE; 1–13). Different lower case letters indicate significant differences between treatments. AG = aboveground; BG = belowground; I = Initial; H = Harvest only; Ts = Topsoil; TsP = Topsoil+Propagules; T = Target. Label numbers refer to Table 1 (No.).

38 **Table S1:** Detailed site description of individual plots. Management: level of mowing frequency per
 39 year; for Initial plots = mowing frequency equivalent to manuring frequency (35-40 kg N ha⁻¹
 40 application-1). Tillage: last time the plot was tilled. Land-use: for Initial plots = recent agricultural
 41 use; for all restored sites = agricultural use before restoration; TG = temporary grassland; PG =
 42 permanent grassland. Mowing: for Initial plots = earliest date of biomass harvesting; for restored and
 43 target sites: earliest date(s) of biomass harvesting based on contracts between farmers and the Nature
 44 Protection Agency of Zurich. Soil type: Soil types based on soil mapping survey 1991 (before
 45 restoration). Slope: slope gradient classes in % according to FAO (1990).

Plot	Treatment	X Coordinate	Y Coordinate	Management	Tillage	Land use	Mowing	Soil type	Slope

47 **Table S2:** Ecosystem attributes, their ecological importance, and their link to selected ecosystem
 48 properties. AG = aboveground; BG = belowground.

Ecosystem attribute	Important indications	Ecosystem property	References
Biodiversity	- Ecosystem stability, resistance and resilience: ability to counteract or buffer environmental changes (e.g. climatic extremes such as droughts or floods); increases rates and pace of recovery from disturbance; acts as barrier to ecological invasion	Arthropod richness AG Taxon richness BG Plant richness	Pennekamp et al. 2018; Isbell et al. 2015; Kennedy et al. 2002; Naeem et al. 2000
Structural diversity	- Niche availability and differentiation: vertical stratification influences important habitat features (i.e., microclimate, food and shelter availability); increased heterogeneity promotes species coexistence and hence species diversity - Spatial heterogeneity: increased patchiness of resources promotes niche differentiation and counteracts homogenization and dominance of exploitative species - Resource utilization efficiency: functional complementary or redundancy of organismic groups indicates sustainability or exploitation of resources; complementary or opposing effects due to enhanced diversity in functional groups	Vegetation structure Soil heterogeneity Functional diversity	Schuldt et al. 2019; Diacon-Bolli et al. 2012; Pacini et al. 2009; Tews et al. 2004 Baer et al. 2019; Gossner et al. 2016 Soliveres et al. 2016; Vandewalle et al. 2010; Pacini et al. 2009; Yachi and Loreau 2007; Rosenfeld 2002
Soil functions	- Presence and diversity of key trophic levels: indicator of disturbance intensity (e.g. restoration method, one-time) or management (ongoing); increased levels of disturbance decrease complexity by absence of higher trophic levels - Water regulation: hydrological conditions (e.g., changes in groundwater level) and water availability for plant growth	Food-web complexity Water holding capacity	Parisi et al. 2005; Bongers 1990 Hazelton and Murphy 2007; Delarze et al. 2015
Soil process	- Storage and filtering capacity: storing, filtering and transforming nutrients and pollutants; regulation of nutrient sequestration and flow to mitigate negative effects of land use or climate change - Soil fertility: capacity of soil to hold and exchange cations in a plant available form; reduced values indicate for potential threat of excessive nutrient-leaching or soil acidification - Nutrient cycling: appropriate levels of plant growth and productivity in sustainable and self-supporting ecosystems	Soil carbon storage Nutrient retention capacity Soil net nitrogen mineralization	Wang et al. 2019; Ward et al. 2016; Grêt-Regamey et al. 2016 Matson et al. 1997 Risch et al. 2018; Risch et al. 2019

49
50

51 **Table S3:** Classification of faunal and microbial functional groups according to which part of the
 52 ecosystem they inhabit (above-/belowground), phylum, identification level of taxonomic or functional
 53 group, feeding type, trophic level, response to increased stress or disturbance levels (SD level), and
 54 the proposed factor defining food-web complexity (FW factor, feeding type + trophic level + SD
 55 level). [Classification of functional groups was based on lowest taxonomic resolution \(see also Data](#)
 56 [repository: <https://doi.org/10.16904/envidat.169>](#). This information was used to assess functional
 57 diversity (feeding type + trophic level) and food-web complexity (rel. abundance multiplied by FW
 58 factor) above- and belowground. Collembola were classified into functional subgroups following
 59 Oliveira Filho et al. (2016). .a = adults; .l = larvae; .juv = juveniles; EMI = ecomorphological index
 60 (Parisi et al. 2005); SD = stress/disturbance level; C-P = colonizer-persister scaling (Bongers 1990).

63 **Table S4:** CoarseSummarized cost categorisation for the 13 ecosystem properties used
 64 to calculate multifunctionality measures. Effort: sampling, extraction and identification (i.e., time
 65 needed). Infrastructure: equipment (e.g., microscopes) and laboratories (e.g., wet, genetic). Analyses
 66 requiring specific equipment, such as (e.g., sequencing machines, CN analyzer) for soil genetic and
 67 chemical properties, have been outsourced to specialised companies as might be most
 68 eligible for practical implementation. Expert knowledge: expertise for identification, classification
 69 and interpretation (e.g., biotic communities). Categories were based on detailed assessment for effort,
 70 infrastructure and expert knowledge listed in Tables S5, S6 and S7. AG = aboveground; BG =
 71 belowground.

Ecosystem property	Cost	Effort	Infrastructure	Expert knowledge
1 Arthropod richness AG	++++ +++ 7+)	++++ +++ +(9+) 9+	+	++

83 **Table S7: Detailed description of the area of expertise needed to assess individual ecosystem**
 84 properties. AG = aboveground; BG = belowground.

<u>Ecosystem property</u>	<u>Area of expertise</u>
<u>1 Arthropod richness AG</u>	- identification and classification of AG arthropods (order to family level)
<u>2 Taxon richness BG</u>	- identification and classification of earthworms (species level) - identification and classification of soil arthropods (order to family level) - identification and classification of soil nematodes (family level) - interpreting metabarcoding data of soil microbes (OTU level)
<u>3 Plant richness</u>	- identification and classification of plants (species level)
<u>4 Vegetation structure</u>	---
<u>5 Soil heterogeneity</u>	- soil chemical, physical, and biogeochemical analysis
<u>6 Functional diversity AG</u>	- see Arthropod richness AG - functional classification of plant species - functional classification of arthropod groups
<u>7 Functional diversity BG</u>	- see Taxon richness BG - functional classification of all biotic groups studied
<u>8 Food-web complexity AG</u>	- see Arthropod richness AG - functional classification of arthropod groups - classification according to taxon response to increased stress or disturbance levels (SD level)
<u>9 Food-web complexity BG</u>	- see Taxon richness BG - functional classification of all biotic groups studied - classification according to taxon response to increased stress or disturbance levels (SD level)
<u>10 Soil carbon storage</u>	---
<u>11 Water holding capacity</u>	---
<u>12 Nutrient retention capacity</u>	---
<u>13 Soil net nitrogen mineralization</u>	- soil chemical and biogeochemical analysis

85

86 **Table S8:** R libraries and packages used for analyses of ecosystem multifunctionality and its single
87 components as well as individual ecosystem properties are listed, indicating reason of analyses.

Analyses	Package	Version	Citation
Beta regression models	betareg	3.1-0	Cribari-Neto & Zeileis et al. 2010
Likelihood ration tests	lmtest	0.9-37	Zeileis & Hothorn 2002
Multiple pairwise comparison and adjustment (univariate)	emmeans	1.3.5	Lenth 2019
	rcompanion	2.2.1	Mangiafico 2019
	multcomp	1.4-10	Hothorn et al. 2008
	multcompView	0.1-7	Graves et al. 2015
Multivariate homogeneity of groups` dispersion	vegan	2.5-5	Oksanen et al. 2019
	permute	0.9-5	Simpson 2019
Strength and significance of Pearson correlation	Hmisc	4.2-0	Harrell 2019
	Formula	1.2-3	Zeileis & Croissant 2010
Exhaustive search (Regression subset selection)	leaps	3.1	Lumley 2020
